# Privacy Preserving Machine Learning via Multi-party Computation 

A THESIS<br>SUBMITTED FOR THE DEGREE OF Master of Technology (ßesearch)<br>IN THE $\mathfrak{F a c u l t y}$ of Engineering<br>BY<br>Harsh Chaudhari

Computer Science and Automation
Indian Institute of Science
Bangalore - 560012 (INDIA)

## Declaration of Originality

I, Harsh Chaudhari, with SR No. 04-04-00-10-22-17-1-14839 hereby declare that the material presented in the thesis titled

## Privacy Preserving Machine Learning via Multi-party Computation

represents original work carried out by me in the Department of Computer Science and Automation at Indian Institute of Science during the years 2017-2020.
With my signature, I certify that:

- I have not manipulated any of the data or results.
- I have not committed any plagiarism of intellectual property. I have clearly indicated and referenced the contributions of others.
- I have explicitly acknowledged all collaborative research and discussions.
- I have understood that any false claim will result in severe disciplinary action.
- I have understood that the work may be screened for any form of academic misconduct.

In my capacity as supervisor of the above-mentioned work, I certify that the above statements are true to the best of my knowledge, and I have carried out due diligence to ensure the originality of the report.

Advisor Name: Arpita Patras

## DEDICATED TO

My beloved

## Aai $\mathcal{G}$ Appa

## Acknowledgements

I would like to begin by thanking my advisor Dr. Arpita Patra for welcoming me to 'Cryptography and Information Security (CRIS)' lab. She is not only my research mentor but also a guardian, teaching me many personal invaluable lessons that I have added to my life. She is a personality with unparalleled research enthusiasm. Her love for the lab members and her ethics are what glued the group together. I am forever indebted to my labmates for the brilliant brainstorming sessions. The cheerful lab atmosphere and the knowledge gained as a result of active detailed discussions was very crucial to the work in my thesis. In particular, I would like to thank Ajith Suresh, my elder research brother, who taught me the art of research and made me interested in this area. I feel supremely fortunate to have got the experience of working closely with him on this project. A shout-out to all my college mates, Swapnil Ghanshyala, Swati Singla, Stanly Samuel, Sanket Purandare, Vyshak PR, Ajinkya Rajput, Bhushan Patil for the support in my entire journey. Lastly, I would like to extend immense love to my familya father who supported me, a mother who was my strength and a sister to whom I could call and talk non-sense forgetting all my worries.

## Abstract

Privacy-preserving machine learning (PPML) via Secure Multi-party Computation (MPC) has gained momentum in the recent past. Assuming a minimal network of pair-wise private channels, we propose an efficient four-party PPML framework over rings $\mathbb{Z}_{2}$, FLASH, the first of its kind in the regime of PPML framework, that achieves the strongest security notion of Guaranteed Output Delivery (all parties obtain the output irrespective of adversary's behaviour). The state of the art ML frameworks such as ABY3 by Mohassel et.al (ACM CCS'18) and SecureNN by Wagh et.al (PETS'19) operate in the setting of 3 parties with one malicious corruption but achieve the weaker security guarantee of abort. We demonstrate PPML with real-time efficiency, using the following custom-made tools that overcome the limitations of the aforementioned state-of-the-art- (a) dot product, which is independent of the vector size unlike the state-of-the-art ABY3, SecureNN and ASTRA by Chaudhari et.al (ACM CCSW'19), all of which have linear dependence on the vector size.(b) Truncation, which is constant round and free of circuits like Ripple Carry Adder (RCA), unlike ABY3 which uses these circuits and has round complexity of the order of depth of these circuits. We then exhibit the application of our FLASH framework in the secure server-aided prediction of vital algorithms- Linear Regression, Logistic Regression, Deep Neural Networks, and Binarized Neural Networks. We substantiate our theoretical claims through improvement in benchmarks of the aforementioned algorithms when compared with the current best framework ABY3. All the protocols are implemented over a 64-bit ring in LAN and WAN. Our experiments demonstrate that, for MNIST dataset, the improvement (in terms of throughput) ranges from $11 \times$ to $1395 \times$ over Local Area Network (LAN) and Wide Area Network (WAN) together.

6.3 Latency of 1 dot product computation for 784 features ..... 56
6.4 Latency for single execution of MSB Extraction protocol ..... 57
6.5 Latency for a single execution of Truncation protocol ..... 58
6.6 Throughput Comparison wrt \# multiplications with truncation ..... 59
6.7 Latency of frameworks for Linear and Logistic Reg. ..... 59
6.8 Latency of frameworks for DNN and BNN ..... 61

## Chapter 1

## Introduction

Secure Multi-party Computation (MPC) [Yao82, BGW88, GMW87, IKNP03, DPSZ12] has evolved over the years in its pursuit of enabling a set of $n$ mutually distrusting parties to compute a joint function $f$, in a way that no coalition of $t$ parties can disrupt the true output of computation (correctness) or learn any information beyond what is revealed by the output of the computation (privacy). The area of secure MPC can be broadly categorized into honest majority [BGW88, MRZ15, ABF ${ }^{+}$16, BJPR18] and dishonest majority [Yao82, DPSZ12, DKL ${ }^{+}$13, MF06, GMW87]. Over the years, MPC has progressed from being simply of theoretical interest to providing real-time practical efficiency. In terms of efficient constructions, the special case of dishonest-majority setting, namely two-party computation (2PC) [Yao82, LP07, Lin16, NO16] has been in limelight over the last decade. However lately, the setting of three parties (3PC) $\left[\mathrm{ABF}^{+} 17, \mathrm{ABF}^{+} 16, \mathrm{MRZ15}, \mathrm{BJPR} 18\right]$ and four parties (4PC) [IKKPC15, BJPR18, GRW18] have drawn phenomenal attention due to the customization in techniques and efficiency that the constructions have to offer. In this direction, the area of MPC in a small domain with an honest majority is quite fascinating due to variety of reasons mentioned below.

First, the most widely known real-time applications such as Danish Sugar-Beet Auction [BCD ${ }^{+}$09], Distributed Credential Encryption [MRZ15], Fair-play MPC [BNP08], VIFF [Gei07], Sharemind [BLW08] explore MPC with 3 parties. Second, the expensive public-key primitives such as Oblivious Transfer (OT) known to be necessary for 2 PC can be eliminated in the honest majority setting. Thus, the resulting constructions use only light-weight primitives and can even be information-theoretically secure. Third, the recent advances in secure Machine Learning (ML) have indicated real-time applications involving a small number of parties [MZ17, MRSV18, WGC19, CCPS19, MR18, AFS19]. Furthermore, the stronger security notions of fairness (the adversary gets the output if and only if the honest parties do) and robustness/guaranteed output delivery (GOD) (all parties obtain the output irrespective of adversary's behavior) are
guaranteed only in the honest majority setting [Cle86].

### 1.1 Related Work

In the regime of MPC over a small domain, interesting works that achieve guaranteed output delivery have been carried out mainly in the class of low-latency (consisting of small constant number of rounds) protocols [PR18, BJPR18, BHPS19]. However, in the view of practical efficiency, high throughput (light in communication and computation complexity) is desirable. Yet the literature of high throughput protocols has seen limited work [GRW18] in guaranteeing security notions stronger than abort. The existing state-of-the-art includes notable works that are highly efficient, but trade security for efficiency $\left[\mathrm{ABF}^{+} 17, \mathrm{AFL}^{+} 16, \mathrm{ABF}^{+} 16, \mathrm{CGH}^{+} 18\right.$, FLNW17, NV18]. In this work, we attempt to bridge the gap between the security achieved and the corresponding efficiency, thus providing highly efficient PPML framework using robust 4 PC as the backbone. Below we summarize the contributions closest to our setting.

The study of MPC in high-throughput networks accelerated with the celebrated work of [DSZ15]. The works of $\left[\mathrm{ABF}^{+} 17, \mathrm{AFL}^{+} 16, \mathrm{ABF}^{+} 16, \mathrm{CGH}^{+} 18\right.$, FLNW17, NV18] swiftly followed. These works focus on the evaluation of arithmetic circuits over rings or finite fields. $\left[\mathrm{AFL}^{+} 16\right]$ is semi-honest and operates over both rings and fields. The works of $\left[\mathrm{ABF}^{+} 17\right.$, FLNW17, DOS18] achieve abort security over rings with one malicious corruption. A compiler to transform semi-honest security to malicious-security was proposed by $\left[\mathrm{CGH}^{+} 18\right]$. This conversion is obtained at twice the cost of the semi-honest protocol. The work of [GRW18] explores 4PC and the security notions of fairness and guaranteed output delivery. However, [GRW18] is dual execution based and relies on expensive public-key primitives and broadcast channel to achieve guaranteed output delivery. [NV18] improvises over $\left[\mathrm{CGH}^{+} 18\right]$ by presenting a batch multiplication technique and additionally explores the notion of fairness.

The influence of ML has found its way in a broad range of areas such as facial recognition [SKP15], banking, medicine [EKN ${ }^{+} 17$ ], recommendation systems and so on. Consequently, technology giants such as Amazon, Google are providing ML as a service (MLaaS) for both training and prediction purposes, where the parties outsource their computation to a set of servers. However, for confidential purposes, government regulations and competitive edge, such data cannot be made publicly available. Thus, there is a need for privacy of data while still enabling customers to perform training and prediction. This need for privacy has given rise to the culmination of MPC and ML. Recent works [MZ17, MR18, MRSV18, WGC19, CCPS19, RWT ${ }^{+}$18] have shown the need of MPC in achieving efficient techniques for privacy-preserving machine learning in server aided setting, where parties outsource their data to a set of servers and the servers compute for purposes of training or prediction. There have been works dedicated
to linear regression [MR18, CCPS19, MZ17], logistic regression [MR18, CCPS19, MZ17] and neural networks [MR18, MZ17, WGC19, JVC18, RWT ${ }^{+}$18] for both training and prediction. The first work to consider secure neural network prediction was the work of Gilad-Barach et al. [DGBL $\left.{ }^{+} 16\right]$, which used homomorphic encryption techniques to provide secure prediction. To improve efficiency of the neural network, they approximated non-linear functions, such as the ReLU activation function to a quadratic function. Since this approximation result led to loss in accuracy, follow up works approximated ReLU using higher degree polynomials $\left[\mathrm{HAJ}^{+} 17\right]$, but incurred higher cost. The work of SecureML [MZ17] provided protocols for secure training and prediction of neural networks with MPC friendly non-linear activation functions, using a combination of arithmetic and garbled circuit techniques. They provided computational security against 2 party ( 2 PC ) one semi-honest corruption setting. The work of MiniONN [LJLA17] further optimized the protocols of SecureML [MZ17] for the case of prediction in 2PC against one semi-honest corruption. Concurrent to this work, the works of Chameleon [ $\mathrm{RWT}^{+} 18$ ] and Gazelle [JVC18] provided secure prediction protocols in the 3PC and 2 PC setting, respectively. Chameleon removed the need of expensive oblivious transfer protocols by using a trusted third party as a dealer, while Gazelle focused on making the linear layers (such as matrix multiplication and convolution) more efficient in terms of communication complexity by providing specialized packing schemes for additively homomorphic encryption schemes. Later ABY3 [MR18] and SecureNN [WGC19] proposed protocols for 3 party against one corruption setting to achieve better throughput (\# queries/sec) by assuming one additional honest party. SecureNN [WGC19] proposed protocols in the semi-honest setting and a new way to tackle division over rings which did not require a division garble circuit as used by earlier works [MZ17] for training and prediction. ABY3 [MR18] took it a step up and proposed a general framework to efficiently switch between the 3 worlds of Arithmetic, Boolean and Yao and showed it's application to neural network training and prediction in the stronger security notion of malicious adversary. Recent works have also dived into variants of neural networks like Deep Neural Networks (DNNs) [MR18, $\left.\mathrm{MMH}^{+} 19, \mathrm{RWT}^{+} 18\right]$, Convolutional Neural Networks (CNNs) [WGC19, RWT ${ }^{+}$18, JVC18], Binarized Neural Networks (BNNs) $\left[\mathrm{KCY}^{+} 18\right]$ and Quantized Neural Networks (QNNs) [ADAM19, JBAP19]. DNNs and CNNs have become one of the most powerful machine learning models in recent history with amount of data available to train them and are one of the most widely considered models for training and prediction tasks for low power devices. MOBIUS $\left[\mathrm{KCY}^{+} 18\right]$ was the first to explore secure prediction in BNNs for semi-honest 2PC. Later [MNBN19] came up with different set of protocols to tackle BNN, but some of the stages in their protocols primarily depended on fields. There have also been substantial work on other machine learning algorithms like decision trees and
k -means clustering. Private decision tree evaluation was first considered in [JPVE07], with application to private evaluation of remote diagnostic programs. Bost et al. [BPTG15] used additively homomorphic encryption to evaluate the decision tree expressed as a polynomial. Recently, Wu et al. [WTMK16], Tai et al. [TMZC17] and Joye and Salehi [JS18] improved the state-of-the-art of private decision tree evaluation protocols. These works relied on additively homomorphic encryption using Diffie-Hellman assumption and presented protocols that achieve security against semi-honest adversaries or malicious clients. Tai et al.[TMZC17] eliminated the dependency (exponential in size) on the depth of the tree that was present in [WTMK16] by representing decision trees as linear functions. This led to enormous improvement when large decision trees were considered. [ÁMJ+19, AFS19] further improved upon [WTMK16] and [TMZC17] and proposed protocols with the non-exponential dependency for secure DT evaluation for 2PC in both semi-honest and malicious setting. Similarly, earlier works on k-means clustering ( $k$-MC) [PR07, GR05] proposed solutions based on MPC, but lacked in efficiency and implementation. Recently, efforts have been made towards a more efficient secure $k$-MC. [SK09] proposed secure $k$-MC for $n$-party setting and [MZR11] tackled $k$-MC in 3PC with one semi honest corruption.

### 1.2 Need for Robustness in Machine Learning

In this work, we strongly motivate the need for robustness in privacy-preserving machine learning as a service (MLaaS) and then go on to explore the setting of 4PC and demonstrate that our constructions are highly efficient compared to the existing state of the art 3PC ML frameworks. The guarantee of robustness is of utmost importance in the area of MLaaS. Consider the following scenario where an entity owns a trained ML model and wants to provide prediction as a service. The model owner outsources her trained model parameters to a set of three servers, which uses one of the aforementioned 3PC ML frameworks for secure prediction. These frameworks keep the privacy of the model parameters and the queries of the clients intact even when one of the servers is maliciously corrupted, but cannot guarantee an output to a given client's query as the adversary can cause the protocol to abort. Thus in the practical setting, one simple strategy of the adversary would be to make the protocol abort for all the client queries. Eventually, this would steer the entity towards loss of monetary value and trust of the clients. The specific problem of MPC with 4-parties tolerating one corruption is of special interest to us. There are three primary motivations for us to consider this setting for achieving GOD(a) avoid theoretical necessity of broadcast channel; (b) avoid expansive public-key primitives and (c) communication efficiency. We elaborate these points below. The popular setting of 3 PC , when considered to achieve robustness, suffers from the necessity of an expensive robust
broadcast channel as proven in the result of [CL14]. By moving to 4PC from 3PC, the need for a broadcast channel is removed, which results in highly efficient constructions [BJPR18] when compared to 3PC [CCPS19, MR18, WGC19]. Additionally in 4PC, for any message sent by a party that needs an agreement, a simple honest majority rule over the residual three parties suffices. Such a property cannot be counted on in 3PC which leads to the use of costly workarounds than 4PC. [GRW18] was the most recent work to propose guaranteed output delivery (robustness) in the 4PC setting. A major concern with GOD variant of multiplication protocol in [GRW18] was utilizing Digital Signatures and expensive public-key primitives: Broadcast and a PKI Setup. Since our end goal is an efficient and robust framework for ML, we let go their approach and propose a simple primitive coupled with a new secret sharing scheme which requires only symmetric-key primitives to achieve robustness.

Moreover, the state-of-the-art 3PC ML frameworks, like ABY3 and ASTRA, focused on highly efficient frameworks for machine learning in the semi-honest setting but suffered from efficiency loss for the primitives dot product, MSB extraction, and truncation in the malicious setting. For example, many of the widely used ML algorithms like Linear Regression, Logistic Regression, and Neural Networks use dot product computation as its building block. While the above frameworks incur a communication cost which is linearly dependent on the underlying size of the feature vector, we are able to eliminate this limitation and provide a dot product protocol whose communication is independent of the vector size. Additionally, we also make almost all our building blocks constant round and free of any circuits, unlike ABY3 which uses expensive non-constant round circuits like Ripple Carry Adder (RCA) in their protocols.

### 1.2.1 Computation over Rings

Lastly, we choose build our framework over rings. Most of the computer architectures, Intel x64 for example, have their primitive data-types over rings. These architectures have specially designed hardware which can support fast and efficient arithmetic operations over rings. This led the way for efficient protocols over rings [BLW08, DOS18, $\mathrm{ABF}^{+} 17$, $\mathrm{EOP}^{+} 19$, CCPS19, $\left.\mathrm{BBC}^{+} 19\right]$ as opposed to fields, which are usually $10-20 \mathrm{x}$ slower since they have to rely on external libraries. Thus, our protocols over rings give the additional advantage of faster performance when implemented in the real-world architectures.

### 1.3 Our Contribution

We propose FLASH, the first robust framework for privacy-preserving machine learning in the four party (4PC) honest majority setting over a ring $\mathbb{Z}_{2}$. We summarize our contributions
below:

### 1.3.1 Robust 4PC protocol

We present an efficient and robust MPC protocol for four parties tolerating one malicious corruption. Concretely, for the multiplication operation, we require an overall communication of just 12 elements in the amortized sense. This is $\approx 2 \times$ improvement in terms of communication over the state-of-the-art protocol of [GRW18]. Moreover, our solution forgoes the need for Digital Signatures and expensive primitives like Broadcast and Public-Key Setup, unlike [GRW18]. The removal of this additional setup of Digital Signatures, PKI and Broadcast primarily comes from two factors - i) a new secret sharing scheme which we call as mirrored-sharing, enables two disjoint sets of parties to perform the computation and perform an effective validation in a single execution, and ii) a simple yet novel bi-convey primitive, which enables two designated parties, say $S_{1}, S_{2}$, to send a value to a designated party $R$ with the help of a fourth party $T$.

The bi-convey primitive guarantees that if both $S_{1}$ and $S_{2}$ are honest, then party $R$ will receive the value $x$ for sure. If not, either the party $R$ will be able to obtain $x$ or both the parties $R$ and $T$ identify that one among $S_{1}, S_{2}$ is corrupt. Our construction for the bi-convey primitive requires a commitment scheme as the only cryptographic tool, which is considered inexpensive. Moreover, the commitments can be clubbed together for several instances and thus the cost of commitment gets amortized as well. Looking ahead, most of our constructions are designed in such a way that every message to be communicated will be made available to at least two parties and thus we can use the bi-convey primitive for the same.

### 1.3.2 Building Blocks for Machine Learning

We propose practically efficient building blocks that form the base for secure prediction. While ABY3 and SecureNN propose building blocks for security with abort, ASTRA elevates the security of these blocks from abort to fairness. We further strengthen the security and make all the building blocks robust. Additionally, we achieve significant efficiency improvements in all the building blocks due to the aid provided by an additional honest party in our setting. The improvements for each block are summarized as follows:

- Dot Product: The aforementioned 3PC frameworks involve communication, linear in the order of vector size, we overcome this limitation with an efficient technique, independent of the vector size. This independence stems from the peculiar structure of our mirrored sharing alongside the multiplication protocol in 4PC.

| Protocol | Equation | ABY3 |  | ASTRA |  | FLASH |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | Rounds | Comm. | Rounds | Comm. | Rounds | Comm. |
| Multiplication | $\llbracket x \rrbracket . \llbracket y \rrbracket \rightarrow \llbracket x . y \rrbracket$ | 5 | $21 \ell$ | 7 | $25 \ell$ | 5 | $12 \ell$ |
| Dot Product | $\llbracket \overrightarrow{\mathbf{x}} \odot \overrightarrow{\mathbf{y}} \rrbracket=\llbracket \sum_{i=1}^{d} \mathrm{x}_{\mathrm{i}} \mathrm{y}_{\mathrm{i}} \rrbracket$ | 5 | $21 m \ell$ | 7 | $23 m \ell+2 \ell$ | 5 | $12 \ell$ |
| MSB Extraction | $\llbracket x \rrbracket \rightarrow \llbracket \mathrm{msb}(\mathrm{x}) \rrbracket^{\mathrm{B}}$ | $\log \ell+5$ | $63 \ell$ | 6 | $\approx 9 \kappa \ell$ | $\log \ell+5$ | $28 \ell$ |
| Truncation | $\llbracket x \rrbracket . \llbracket y \rrbracket \rightarrow \llbracket(x y)^{t} \rrbracket$ | $2 \ell-1$ | $\approx 108 \ell$ | - | - | 5 | $14 \ell$ |
| Bit Conversion | $\llbracket b \rrbracket^{\mathbf{B}} \rightarrow \llbracket b \rrbracket$ | 6 | $42 \ell$ | - | - | 5 | $14 \ell$ |
| Bit Insertion | $\llbracket b \rrbracket^{\mathbf{B}} \llbracket \times \rrbracket \rightarrow \llbracket b \mathrm{x} \rrbracket$ | 7 | $63 \ell$ | - | - | 5 | $18 \ell$ |

Table 1.1: Comparison of FLASH framework with ABY3 and ASTRA; $\ell, \kappa$ and $m$ denote the ring size, security parameter and number of features respectively.

- Truncation: Overflow caused by repeated multiplications may cause accuracy loss which can be prevented with truncation. Truncation has been expensive in the 3PC framework, especially ABY3 uses a Ripple Carry Adder (RCA) circuit which consumes around 108 ring elements to achieve MSB Extraction. We propose a simple yet efficient technique with a total of just 14 ring elements and does not require any circuits. The technical novelty comes from the specific roles played by the parties, in conjunction with the multiplication protocol of 4PC. We defer the detailed analysis of our truncation protocol and the corresponding roles of the parties to Section 4.4.
- MSB Extraction: Comparing two arithmetic values in a privacy-preserving manner is one of the major hurdles in realizing efficient privacy-preserving ML algorithms. The state of the art SecureML[MZ17] and ABY3 made an effort in this direction with the use of a garbled circuit technique and a boolean parallel prefix adder (PPA) respectively. We extend the technique proposed by ABY3 of using a boolean PPA circuit for our 4PC setting. We provide a detailed analysis in Section 4.3 of how the boolean PPA circuit is instantiated in our setting.
- Bit Conversion and Insertion: Operating interchangeably in the arithmetic and boolean worlds often demand conversion of a boolean bit to its arithmetic equivalent (bit conversion) or the multiplication of a boolean bit with an arithmetic value (bit insertion). We propose efficient techniques to achieve the same with innovations coming from our mirrored secret sharing and its linearity property. Ours is the first work in 4PC that proposes these transformations and is even superior to the state-of-the-art 3PC ML frameworks ABY3 and ASTRA, in terms of both efficiency and security guarantee. Table 1.1 provides
a detailed comparison in terms of communication (Comm.) and rounds with ABY3 and ASTRA.

### 1.3.3 Secure Prediction

We aim at secure prediction in a server-aided setting. Here, the model owner ( $M$ ) holds a set of trained model parameters which are used to predict output to client's $(C)$ input query, while preserving the privacy of the inputs of both the parties. The servers perform computation and reconstruct the output towards the client. Security is provided against a malicious adversary corrupting one server along with either model owner or client. We extend our techniques for vital machine learning algorithms namely: i) Linear Regression, ii) Logistic Regression, iii) Deep Neural Network (DNN) and iv) Binarized Neural Network (BNN). While Linear Regression is extensively used in Market Analytics, Logistic Regression is used in a variety of applications like customer segmentation, insurance fraud detection and so on. Despite being computationally cheap and smaller in size, the performance accuracy of BNNs is comparable to that of deep neural networks. They are the go-to networks for running neural networks on low-end devices. These use cases exhibit the importance of these algorithms in real-time and we make an effort to efficiently perform the secure evaluation for these algorithms.

| ML Algorithm | Setting |  |
| :--- | ---: | ---: |
|  | LAN | WAN |
| Linear Regression | $1395 \times$ | $124 \times$ |
| Logistic Regression | $400 \times$ | $29 \times$ |
| Deep Neural Network | $314 \times$ | $13 \times$ |
| Binarized Neural Network | $268 \times$ | $11.5 \times$ |

Table 1.2: Improvement over ABY3 in terms of throughput for MNIST dataset

We provide implementation results for all our protocols over a ring $\mathbb{Z}_{2}{ }^{64}$. We summarize the efficiency gain of our protocols over the state-of-the-art ABY3 and ASTRA, albeit more elaborate details follow in Section 6.2. The latency and throughput (the number of operations per unit time) of the protocols are measured in the LAN (1Gbps) and WAN (20Mbps) setting while communication complexity is measured independent of the network.

The improvements for DNN and BNN stated in Table 1.2 are for a network having 2 hidden layers, each layer consisting of 128 nodes. Table 1.2 clearly shows that apart from making the building blocks robust, our framework also achieves impressive improvements over ABY3 framework.

### 1.3.4 Extension to 4PC Abort

As an extension, we also propose protocols for the weaker abort setting (honest parties abort if the adversary deviates from the protocol). The abort variant for the aforementioned protocols are achieved by simply tweaking the bi-convey primitive present in the robust protocols. We give a detailed analysis and comparison with state-of-the-art works in Section 4.7.

### 1.4 Organization of Thesis:

The thesis is written as follows:
i) We begin by introducing the preliminaries in chapter 2 where we define our security model and the security notion of Guaranteed Output Delivery. We also briefly describe well defined primitives like collision resistant hash function, commitment scheme, etc.
ii) Chapter 3 begins with description of our new sharing scheme called "mirrored sharing". We then describe the construction of our "Bi-Convey" primitive that acts as the backbone for all our protocols. The protocols for addition and multiplication are also described in the same chapter.
iii) Chapter 4 provides the details of ML building blocks such as dot product, MSB extraction, truncation, etc which are essential for our robust machine learning framework.
iv) The final chapter provides the benchmarking results of our framework for different datasets over LAN and WAN setting strengthening our earlier claims.

## Chapter 2

## Preliminaries

We consider a set of four parties $\mathcal{P}=\left\{\mathrm{V}_{1}, \mathrm{~V}_{2}, \mathrm{E}_{1}, \mathrm{E}_{2}\right\}$ connected by pair-wise private and authentic channels in a synchronous network. $E_{1}, E_{2}$ define the role of the parties as evaluators in the computation while parties $V_{1}, V_{2}$ enact the role of verifiers in the computation. We use $\mathbf{E}$ and $\mathbf{V}$ to denote the set of evaluators $\left\{\mathrm{E}_{1}, \mathrm{E}_{2}\right\}$ and verifiers $\left\{\mathrm{V}_{1}, \mathrm{~V}_{2}\right\}$ respectively. The function $f$ to be evaluated is expressed as a circuit ckt, with a publicly known topology and is evaluated over either an arithmetic ring $\mathbb{Z}_{2^{\ell}}$ or a Boolean ring $\mathbb{Z}_{2^{1}}$, consisting of 2-input addition and multiplication gates. d denotes the multiplicative depth of ckt. We also use a collision-resistant hash function, denoted by H() and a commitment scheme, denoted by com () , in our protocols for practical efficiency. The details of the same can be found in Section 2.3 and 2.4 respectively.

### 2.1 Security Model:

For MPC, each party is modelled as a non-uniform probabilistic polynomial time (PPT) interactive Turing Machine. We operate in a static security model with an honest majority, where a PPT adversary $\mathcal{A}$ can corrupt a party at the onset of the protocol. $\mathcal{A}$ can be malicious in our setting i.e, the corrupt parties can arbitrarily deviate from the protocol specification. The computational security parameter is denoted by $\kappa$.

### 2.1.1 Robustness or Guaranteed Output Delivery:

A protocol is said to be robust if all the parties can compute the output of the protocol irrespective of the behaviour of the adversary. We prove the security of our protocols in the standard real/ideal world paradigm where we compare the view of the adversary in the real world and ideal world. In an ideal world execution, each party sends its input to an incorruptible trusted third party (TTP), who computes the given function $f(\cdot)$ using the inputs received and sends back the respective output to each party. The ideal world execution involves a set of parties $\mathcal{P}$,
where $|\mathcal{P}|=4$, an ideal adversary $\mathcal{S}$ who may corrupt one of the parties, and a functionality $\mathcal{F}$. The real world execution involves the PPT set of parties $\mathcal{P}$, and a real world adversary $\mathcal{A}$ who may corrupt at most one of the parties. We let $\operatorname{IDEAL}_{\mathcal{F}, \mathrm{s}}\left(1^{\kappa}, z\right)$ denote the output of the honest parties and the view of the ideal-world adversary $\mathcal{S}$ from the ideal execution with respect to the security parameter $1^{\kappa}$ and auxiliary input $z$. Similarly, let $\operatorname{REAL}_{\pi, \delta}\left(1^{\kappa}, z\right)$ denote the output of the honest parties and the view of the adversary $\mathcal{A}$ from the real execution with respect to the security parameter and auxiliary input $z$. We say that $\pi$ securely realizes $\mathcal{F}$ if for every PPT real world adversary $\mathcal{A}$, there exists a PPT ideal world adversary $\mathcal{S}$, corrupting the same parties, such that the following two distributions are computationally indistinguishable $\operatorname{IDEAL}_{\mathcal{F}, s} \stackrel{c}{\approx} \mathrm{REAL}_{\pi, s}$. We define an ideal world functionality $\mathcal{F}_{\text {robust }}$ that realizes a function $f$ with guaranteed output delivery in the 4PC setting in Fig 2.1 below.
$\mathcal{F}_{\text {robust }}$ receives input (Input, $x$ ) from party $P \in\left\{\mathrm{~V}_{1}, \mathrm{~V}_{2}, \mathrm{E}_{1}, \mathrm{E}_{2}\right\}$. While honest parties send their input correctly, corrupt parties may send arbitrary inputs as instructed by the adversary $\mathcal{A}$.

- For every party $P, \mathcal{F}_{\text {robust }}$ sets $x$ to some predetermined value if either $x=*$ or $x$ is outside the domain of values allowed for input of $P$.
$-\mathcal{F}_{\text {robust }}$ computes output $y=f\left(x_{1}, x_{2}, x_{3}, x_{4}\right)$ and sends (Output, $y$ ) to all the parties in $\left\{\mathrm{V}_{1}, \mathrm{~V}_{2}, \mathrm{E}_{1}, \mathrm{E}_{2}\right\}$.

Figure 2.1: Functionality $\mathcal{F}_{\text {robust }}$ for 4PC protocol

### 2.2 Shared Key Setup:

We adopt a one-time key setup to minimize the overall communication of the protocol. We use three types of key setup namely, between i) a pair of parties, ii) a committee of three parties and iii) all the four parties. In each type, the parties in consideration can run an MPC protocol to agree on a randomness and use it as the key for pseudo-random function (PRF) to derive any subsequent co-related randomness. We model the protocol for the shared key setup as functionality $\mathcal{F}_{\text {setup }}$ (Fig 2.2) that establishes the shared randomness among the 4 parties $\left(\mathrm{V}_{1}, \mathrm{~V}_{2}, \mathrm{E}_{1}, \mathrm{E}_{2}\right)$.

[^0]$-\mathrm{y}_{i}=\left(k_{\mathbf{E}}, k_{\mathrm{V}, \mathrm{E}_{2}}, k_{\mathbf{E}, \mathrm{V}_{1}}, k_{\mathbf{E}, \mathrm{V}_{2}}, k_{\mathcal{P}}\right)$ when $P_{i}=\mathrm{E}_{2}$.
Output: $\mathcal{F}_{\text {setup }}$ sends the keys $\mathrm{y}_{i}$ to party $P_{i}$.
Figure 2.2: Functionality $\mathcal{F}_{\text {setup }}$

### 2.3 Collision Resistant Hash:

Consider a hash function family $\mathrm{H}=\mathcal{K} \times \mathcal{L} \rightarrow y$. The hash function H is said to be collision resistant if for all probabilistic polynomial-time adversaries $\mathcal{A}$, given the description of $\mathrm{H}_{k}$ where $k \in_{R} \mathcal{K}$, there exists a negligible function negl () such that $\operatorname{Pr}\left[\left(x_{1}, x_{2}\right) \leftarrow \mathcal{A}(k):\left(x_{1} \neq\right.\right.$ $\left.\left.x_{2}\right) \wedge \mathrm{H}_{k}\left(x_{1}\right)=\mathrm{H}_{k}\left(x_{2}\right)\right] \leq \operatorname{neg}(\kappa)$, where $m=\operatorname{poly}(\kappa)$ and $x_{1}, x_{2} \in_{R}\{0,1\}^{m}$.

### 2.4 Commitment Scheme:

We use $\operatorname{com}(x)$ to denote commitment of a value $x$. The commitment scheme (com()) possess two properties, namely - i) hiding, which ensures the privacy of value $x$ given just the commitment, and ii) binding, which prevents a corrupt party from opening the commitment to a different value $x^{\prime} \neq x$. The commitment scheme can be implemented via a hash function $\mathcal{H}()$, whose security can be proved in the random-oracle model (ROM). For example, $(c, o)=(\mathcal{H}(x \| r), x \| r)=\operatorname{Com}(x ; r)$.

## Chapter 3

## Robust 4PC

In this section, we present a robust and efficient 4PC protocol with security against one malicious adversary. Our protocol incurs 12 ring elements per multiplication and removes the need for any additional setup of Broadcast, Digital Signatures, and Public-Key Setup, unlike [GRW18]. We begin this section by introducing our sharing semantics followed by giving a high level overview of our input sharing phase of our protocol. We then introduce our most crucial building block "bi-convey primitive", which forms the core for the majority of our constructions. As mentioned in the introduction, bi-convey primitive enables two designated parties to send a value $x$ to the third party with the aid of fourth party. The remainder of the section describes a high-level overview of our circuit evaluation and output computation stages of our protocol.

### 3.1 Sharing Semantics

We use additive secret sharing of secrets over either an arithmetic ring $\mathbb{Z}_{2^{\ell}}$ or a Boolean ring $\mathbb{Z}_{2^{1}}$. We define two variants of secret sharing that are used in this work.

- Additive sharing ([•]-sharing): A value $x$ is additively shared between two parties if $x=x^{1}+x^{2}$, where one party holds the first share $x^{1}$ while the other party holds $x^{2}$. We use $[x]=\left(x^{1}, x^{2}\right)$ to denote $[\cdot]$-sharing of $x$.
- Mirrored sharing ( $\llbracket \rrbracket \rrbracket$-sharing): A value $x$ is said to be $\llbracket \cdot \rrbracket$-shared among the parties in $\mathcal{P}$ if:
- There exist values $\sigma_{x}, \mu_{x}$ such that $\mu_{x}=x+\sigma_{x}$.
- $\sigma_{x}$ is $[\cdot]$-shared among parties in $\mathbf{E}$ as $\left[\sigma_{x}\right]_{\mathrm{E}_{1}}=\sigma_{x}^{1}$ and $\left[\sigma_{x}\right]_{\mathrm{E}_{2}}=\sigma_{x}^{2}$, while parties in $\mathbf{V}$ hold both $\sigma_{x}^{1}$ and $\sigma_{x}^{2}$.
- $\mu_{x}$ is $[\cdot]$-shared among parties in $\mathbf{V}$ as $\left[\mu_{x}\right]_{\mathrm{V}_{1}}=\mu_{x}^{1}$ and $\left[\mu_{x}\right] \mathrm{V}_{2}=\mu_{x}^{2}$, while parties in $\mathbf{E}$ hold both $\mu_{x}^{1}$ and $\mu_{x}^{2}$.

The shares of each party can be summarized as:

$$
\begin{array}{ll}
\mathrm{E}_{1}: \llbracket x \rrbracket_{\mathrm{E}_{1}}=\left(\sigma_{x}^{1}, \mu_{x}^{1}, \mu_{x}^{2}\right) & \mathrm{V}_{1}: \llbracket x \rrbracket_{\mathrm{V}_{1}}=\left(\sigma_{x}^{1}, \sigma_{x}^{2}, \mu_{x}^{1}\right) \\
\mathrm{E}_{2}: \llbracket x \rrbracket_{\mathrm{E}_{2}}=\left(\sigma_{x}^{2}, \mu_{x}^{1}, \mu_{x}^{2}\right) & \mathrm{V}_{2}: \llbracket x \rrbracket_{\mathrm{V}_{2}}=\left(\sigma_{x}^{1}, \sigma_{x}^{2}, \mu_{x}^{2}\right)
\end{array}
$$

We use the notation $\llbracket x \rrbracket=\left(\left[\sigma_{x}\right],\left[\mu_{x}\right]\right)$ to denote $\llbracket \cdot \rrbracket$-sharing of value $x$. Sharing techniques and protocols for the boolean variant $\left(\mathbb{Z}_{2^{1}}\right)$ are identical to their arithmetic counterparts apart from addition and subtraction operations being replaced with XOR and multiplication with AND. We use $\llbracket \cdot \rrbracket^{B}$ to denote the sharing over a boolean ring. Unless specified, the sharing is done over $\mathbb{Z}_{2}{ }^{\ell}$.

- Linearity of $[\cdot]$-sharing and $\mathbb{[ \cdot ]}$-sharing: Given $[x]=\left(x^{1}, x^{2}\right),[y]=\left(y^{1}, y^{2}\right)$ and public constants $c_{1}, c_{2} \in \mathbb{Z}_{2}$ e, we have

$$
\left[c_{1} x+c_{2} y\right]=\left(c_{1} x^{1}+c_{2} y^{1}, c_{1} x^{2}+c_{2} y^{2}\right)=c_{1}[x]+c_{2}[y]
$$

Thus, $\left[c_{1} x+c_{2} y\right]$ and $c_{1}[x]+c_{2}[y]$ are equivalent and implies that parties can compute shares of any linear function of [.]-shared values locally. It is easy to see that the linearity property extends to our $\llbracket \cdot \rrbracket$-sharing as well.

### 3.2 Input Sharing

The goal is to robustly generate a $\llbracket \cdot \rrbracket$-sharing of a party's input. We call a party who wants to share the input as a Dealer. On a high level, if a dealer D wants to share a value $x$, parties start by locally sampling $\sigma_{x}^{1}, \sigma_{x}^{2}$ and $\mu_{x}^{1}$, according to the defined sharing semantics. The dealer then sets the last share as $\mu_{x}^{2}=x+\sigma_{x}-\mu_{x}^{1}$. In case when the dealer is a verifier (say $\mathrm{V}_{1}$ ), we enforce $\mathrm{V}_{1}$ to send $\mu_{x}^{2}$ to both the evaluators and $\operatorname{com}\left(\mu_{x}^{2}\right)$ to $\mathrm{V}_{2}$. Now, all parties except $\mathrm{V}_{1}$, exchange $\operatorname{com}\left(\mu_{x}^{2}\right)$ and compute the majority. If there exists no majority then $\mathrm{V}_{1}$ is known to be corrupt and eliminated from the computation. The remaining parties can then run a semi-honest three-party protocol to compute the output. A similar idea follows for the case when the dealer is an evaluator. We provide the formal details of our $\Pi_{\mathrm{sh}}$ and the corresponding ideal functionality $\mathcal{F}_{\text {sh }}$ in Fig 3.2 and Fig 3.1 respectively.

- $\mathcal{F}_{\text {sh }}$ receives $x$ from party/dealer D who wants to generate $\llbracket \cdot \rrbracket$-sharing of $x$. Other parties input $\perp$ to the functionality.
- $\mathcal{F}_{\text {sh }}$ randomly samples $\sigma_{x}^{1}, \sigma_{x}^{2}$ and $\mu_{x}^{1} \in \mathbb{Z}_{2^{\ell}}$ and set $\mu_{x}^{2}=x+\sigma_{x}^{1}+\sigma_{x}^{2}-\mu_{x}^{1}$.
- The output shares sent by $\mathcal{F}_{\text {mul }}$ are as follows:

$$
\begin{aligned}
& \mathrm{V}_{1}:\left(\sigma_{x}^{1}, \sigma_{x}^{2}, \mu_{x}^{1}\right), \mathrm{V}_{2}:\left(\sigma_{x}^{1}, \sigma_{x}^{2}, \mu_{x}^{2}\right) \\
& \mathrm{E}_{1}:\left(\sigma_{x}^{1}, \mu_{x}^{1}, \mu_{x}^{2}\right), \mathrm{E}_{2}:\left(\sigma_{x}^{2}, \mu_{x}^{1}, \mu_{x}^{2}\right)
\end{aligned}
$$

- Dealer D also receives the fourth missing share from $\mathcal{F}_{\text {sh }}$

Figure 3.1: Functionality $\mathcal{F}_{\text {sh }}$ : Ideal Functionality for Input Sharing of $x$

- Input: Party D inputs value $x$ while others input $\perp$.
- Output: Parties obtain $\llbracket x \rrbracket$ as the output.
- If $\mathrm{D}=\mathrm{E}_{1}$ : Parties in $\mathbf{V}$ and $\mathrm{E}_{1}$ locally sample $\sigma_{x}^{1}$, while all the parties in $\mathcal{P}$ locally sample $\sigma_{x}^{2}$. Parties in $\mathbf{V}$ and $\mathbf{E}_{1}$ locally compute $\sigma_{x}=\sigma_{x}^{1}+\sigma_{x}^{2}$. Similar steps are done for $D=\mathrm{E}_{2}$.
- If $\mathrm{D}=\mathrm{V}_{i}$ for $i \in\{1,2\}$ : Parties in $\mathbf{V}$ and $\mathrm{E}_{1}$ locally sample $\sigma_{x}^{1}$, while parties in $\mathbf{V}$ and $\mathrm{E}_{2}$ locally sample $\sigma_{x}^{2}$. Parties in $\mathbf{V}$ locally compute $\sigma_{x}=\sigma_{x}^{1}+\sigma_{x}^{2}$.
- If $\mathrm{D}=\mathrm{V}_{1}$ : Party $\mathrm{V}_{1}$ computes $\mu_{x}=x+\sigma_{x}$. Parties in $\mathbf{E}$ and $\mathrm{V}_{1}$ locally sample $\mu_{x}^{1}$. Party $\mathrm{V}_{1}$ computes and sends $\mu_{x}^{2}=\mu_{x}-\mu_{x}^{1}$ to parties in $\mathbf{E}$ and $\bigvee_{2}$. Parties in $\mathbf{E}$ and $\bigvee_{2}$ exchange the received copy of $\mu_{x}^{2}$. If there exists no majority, then they identify $\mathrm{V}_{1}$ to be corrupt and engage in semi-honest 3PC excluding $\mathrm{V}_{1}$ (with default input for $\mathrm{V}_{1}$ ). Else, they set $\mu_{x}^{2}$ to the computed majority. Similar steps are done for $D=\mathrm{V}_{2}$.
- If $\mathrm{D}=\mathrm{E}_{i}$ for $i \in\{1,2\}$ : Party $\mathrm{E}_{i}$ computes $\mu_{x}=x+\sigma_{x}$. Parties in $\mathbf{E}$ and $\mathrm{V}_{1}$ locally sample $\mu_{x}^{1}$. Party $\mathrm{E}_{i}$ computes and sends $\mu_{x}^{2}=\mu_{x}-\mu_{x}^{1}$ to $\mathrm{V}_{2}$ and the co-evaluator. $\mathrm{E}_{i}$ sends com $\left(\mu_{x}^{2}\right)$ to $\mathrm{V}_{1}$. Parties other than the dealer exchange the commitment of $\mu_{x}^{2}$ to compute majority (the co-evaluator and $\bigvee_{2}$ also exchange their copies of $\mu_{x}^{2}$ ). If no majority exists, then they identify $\mathrm{E}_{i}$ to be corrupt and engage in semi-honest 3PC excluding $\mathrm{E}_{i}$ (with default input for $\mathrm{E}_{i}$ ). Else, they set $\mu_{x}^{2}$ to the computed majority.

Figure 3.2: $\Pi_{\text {sh }}(\mathrm{D}, x)$ : Protocol to generate $\llbracket x \rrbracket$ by dealer D .
Lemma 1. Each party either commits to his/her input in $\Pi_{\text {sh }}$ or is identified to be corrupt.
Proof. In $\Pi_{\text {sh }}$, the mirrored sharing of inputs by each party is as in $\Pi_{\text {sh }}$ with an additional step of identifying the adversary in case of mismatch. The step of eliminating the adversary uses the computation of honest majority on the dispersed shares. Since only, one corruption can occur, an honest party's input always gets committed irrespective of the behavior of the adversary. However, the case of no honest majority can occur only when the dealer is corrupt. Hence only a corrupt party is eliminated if she does not commit to her input and a default value is taken.

The uniqueness of the share also follows from collision resistant hash. Else, the chosen input is committed.

### 3.2.1 Security of Input Sharing

We begin by first discussing the general strategy of simulation for the entire circuit to tackle the corrupt party. The simulator $\mathcal{S}$ for the entire circuit begins by simulating the $\mathcal{F}_{\text {setup }}$ functionality and giving the keys to the adversary. This way the keys used in the PRF setup by the corrupt party during the course of circuit evaluation is also known to the simulator. During the input sharing phase the simulator on receiving the input shares from the corrupt party, on behalf of the honest parties, is able to extract the adversary's input using the keys given to him. This is possible because the inputs of each party are shared in mirrored sharing format (Section 3.1). Additionally the simulator, on behalf of the honest parties set their inputs as 0 . The simulator $\mathcal{S}$ now knows the inputs of all the parties and can compute all the intermediate values of each one of the building block in the circuit as well as the final output of the circuit in clear. Additionally the corrupt party receives only the input shares of the honest parties and hence cannot distinguish if the underlying value was 0 (received from the simulator) or the true values of the honest parties.

In this section, we describe a detailed security proof for our $\Pi_{\text {sh }}$ protocol. Specifically, we prove Theorem 1 in the $\mathcal{F}_{\text {setup }}$ hybrid model.

Theorem 1. Assuming one-way functions, the protocol $\Pi_{\text {sh }}$ securely realizes the functionality $\mathcal{F}_{\text {sh }}$ in the $\mathcal{F}_{\text {setup }}$ hybrid model against one malicious corruption in the standard model.

We describe the simulator for the case of a corrupt $\mathrm{V}_{1}$ and a corrupt $\mathrm{E}_{1}$. Other cases are similar to these and hence can be worked out in a similar way.

1) If $\mathrm{D}=\mathrm{E}_{1}, \delta_{\Pi_{\text {sh }}}^{\mathrm{V}_{1}}$ samples $\sigma_{x}^{1}$ on behalf of $\mathrm{V}_{2}$ and $\mathrm{E}_{1}$ and samples $\sigma_{x}^{2}$ on behalf of all honest parties respectively to compute $\sigma_{x}=\sigma_{x}^{1}+\sigma_{x}^{2}$. Similar steps are done for $\mathrm{D}=\mathrm{E}_{2}$.
2) If $\mathrm{D}=\mathrm{V}_{1}, \mathcal{S}_{\Pi_{\text {sh }}}^{\mathrm{V}_{1}}$ samples $\sigma_{x}^{1}$ and $\sigma_{x}^{2}$ on behalf of $\mathrm{V}_{2}, \mathrm{E}_{1}$ and $\mathrm{V}_{2}, \mathrm{E}_{2}$ respectively to compute $\sigma_{x}=\sigma_{x}^{1}+\sigma_{x}^{2}$. Similar steps are done for $\mathrm{D}=\mathrm{V}_{2}$.
3) If $\mathrm{D}=\mathrm{V}_{1}, \mathcal{S}_{\Pi_{\text {sh }}}^{\mathrm{V}_{1}}$ samples $\mu_{x}^{1}$ on behalf of $\mathrm{E}_{1}, \mathrm{E}_{2}$. Receive $\mu_{x}^{2}$ from $\mathrm{V}_{1}$ on behalf of all honest parties. If the received copies have no majority, set flag $=1$.

- If flag $=1: \mathcal{S}_{\Pi_{1}}^{\boldsymbol{V}_{1}}$ sets the input of $\mathrm{V}_{1}$ as $x=0$ (default value) and executes a semi-honest 3 PC on behalf of the remaining three honest parties. $\mathcal{S}_{\Pi_{\mathrm{sh}}}^{V_{1}}$ then sends the final output to $V_{1}$.
- Else If flag $=0: \mathcal{S}_{\Pi_{\text {sh }}}^{\vee_{1}}$ extracts the input of $\mathrm{V}_{1}$ by computing $x=\mu_{x}-\sigma_{x}$ and invokes $\mathcal{F}_{\text {sh }}$ with input as $x$ on behalf of $\mathrm{V}_{1}$.

4) If $\mathrm{D}=\mathrm{V}_{2}$, locally sample $\mu_{x}^{1}$ on behalf of parties in $\mathbf{E}$ and $\mathrm{V}_{2}$. Send $\operatorname{com}\left(\mu_{x}^{2}\right)$ to $\mathrm{V}_{1}$ on behalf of $\mathrm{V}_{2}, \mathrm{E}_{1}, \mathrm{E}_{2}$ on a random $\mu_{x}^{2}$. Similar steps are done for $\mathrm{D}=\mathrm{E}_{i}, i \in\{1,2\}$.

Figure 3.3: $\mathcal{S}_{\Pi_{s h}}^{\bigvee_{1}}$ : Simulator for corrupt $\bigvee_{1}$ in $\Pi_{\text {sh }}$
This completes the simulation for the case of a corrupt $\mathrm{V}_{1}$. We now describe the simulator for the case of a corrupt $E_{1}$.

1) If $\mathrm{D}=\mathrm{E}_{1}, \mathcal{S}_{\Pi_{\text {sh }}}^{\mathrm{E}_{1}}$ samples $\sigma_{x}^{1}$ on behalf of verifiers and samples $\sigma_{x}^{2}$ on behalf of verifiers and $\mathrm{E}_{2}$ to compute $\sigma_{x}=\sigma_{x}^{1}+\sigma_{x}^{2}$. Similar steps are done for $\mathrm{D}=\mathrm{E}_{2}$.
2) If $\mathrm{D}=\mathrm{V}_{i}, i \in[2]$, sample $\sigma_{x}^{1}$ and $\sigma_{x}^{2}$ on behalf of verifiers and $\mathrm{E}_{2}$ to compute $\sigma_{x}=\sigma_{x}^{1}+\sigma_{x}^{2}$.
3) If $\mathrm{D}=\mathrm{E}_{1}, \mathcal{S}_{\Pi_{\text {sh }}}^{\mathrm{E}_{1}}$ samples $\mu_{x}^{1}$ on behalf of $\mathrm{V}_{1}, \mathrm{E}_{2}$ and receives $\mu_{x}^{2}$ from $\mathrm{E}_{1}$ on behalf of $\mathrm{V}_{2}, \mathrm{E}_{2}$ and $\operatorname{com}\left(\mu_{x}^{2}\right)$ on behalf of $\bigvee_{1}$. If there exists no majority, set flag $=1$.

- If flag $=1: \mathcal{S}_{\Pi_{\text {sh }}}^{\mathrm{E}_{1}}$ sets the input of $\mathrm{E}_{1}$ as $x=0$ (default value) and executes a semihonest 3 PC on behalf of the remaining three honest parties. $\mathcal{S}_{\Pi_{\text {sh }}}^{\mathrm{E}_{1}}$ then sends the final output to $E_{1}$.
- Else if flag $=0: \mathcal{S}_{\Pi_{\text {sh }}}^{\mathrm{E}_{1}}$ extracts the input of $\mathrm{E}_{1}$ by computing $x=\mu_{x}-\sigma_{x}$ and invokes $\mathcal{F}_{\text {sh }}$ with input $x$ on behalf of $\mathrm{E}_{1}$.

4) If $\mathrm{D}=\mathrm{E}_{2}$, locally sample $\mu_{x}^{1}$ on behalf of parties in $\mathrm{E}_{2}$ and $\mathrm{V}_{2}$. Send $\mu_{x}^{2}$ to $\mathrm{E}_{1}$ on behalf of $\mathrm{E}_{2}$ on a random $\mu_{x}^{2}$. Also, send $\operatorname{com}\left(\mu_{x}^{2}\right)$ to $\mathrm{E}_{1}$ on behalf of $\mathrm{V}_{2}, \mathrm{~V}_{1}$. Similar steps are done for $\mathrm{D}=\mathrm{V}_{i}, i \in\{1,2\}$.

Figure 3.4: $\mathcal{S}_{\Pi_{\text {sh }}}^{\mathrm{E}_{1}}$ : Simulator for corrupt $\mathrm{E}_{1}$ in $\Pi_{\text {sh }}$

### 3.3 Bi-Convey Primitive

Bi-convey primitive enables either i) two parties, say $S_{1}, S_{2}$, to convey a value $x \in \mathbb{Z}_{2^{\ell}}$ to a designated party $R$ or ii) allows party $R$ to identify that one among $S_{1}, S_{2}$ is corrupt. The technical innovation of our construction for the 4 party case lies in using the fourth party available, say $T$, in an efficient manner. To elaborate, the protocol proceeds as follows. Parties $S_{1}, S_{2}$ both send the value $x$ to $R$. In parallel, they send a commitment of the same (com $\left.(x)\right)$ to the fourth party $T$. Note that the randomness used to prepare the commitment is picked from the common source of the randomness of $S_{1}, S_{2}$ and $R$. If the received copies of $x$ match, party $R$ accepts the value and sends continue to $T$, and discards any message received from $T$. If
not, $R$ will identify that one among $\left(S_{1}, S_{2}\right)$ is corrupt and thus $T$ is honest. She then sends her internal randomness to $T$ and waits for a message from $T$. Note that, the internal randomness of $R$ which is forwarded to $T$, in our setting are all the keys of $R$ (established during the shared key setup phase) that are not available with $T$. Party $T$, on the other hand, first checks if the commitments received from $S_{1}, S_{2}$ match or not. If they match, she will forward $\operatorname{com}(x)$ to $R$ else, she will identify that one among $\left(S_{1}, S_{2}\right)$ is corrupt and thus sends her internal randomness to $R$. Now, if $R$ receives $\operatorname{com}(x)$ from $T$, then she will accept the version of $x$ that matches with the received $\operatorname{com}(x)$ and stops. If not, then both $R$ and $T$ have identified that one among $\left(S_{1}, S_{2}\right)$ is corrupt. The formal protocol appears in Figure 3.6 and the details for corresponding ideal world functionality $\mathcal{F}_{\text {bic }}$ appears in Figure 3.5.
$\mathcal{F}_{\text {bic }}$ receives $x, x^{\prime}, \mathbf{I}_{R}$ and $\mathbf{I}_{T}$ from the parties $S_{1}, S_{2}, R$ and $T$ respectively. Here $\mathbf{I}_{R}$ and $\mathbf{I}_{T}$ denote the internal randomness of parties $R$ and $T$ respectively. $\mathcal{F}_{\text {bic }}$ sets $\operatorname{msg}_{S_{1}}=\operatorname{msg}_{S_{2}}=\perp$.

- If $x=x^{\prime}$, then $\mathcal{F}_{\text {bic }}$ sets $\mathrm{msg}_{T}=\perp$ and $\operatorname{msg}_{R}=x$. Else it sets $\mathrm{msg}_{T}=\mathrm{I}_{R}$ and $\mathrm{msg}_{R}=\mathrm{I}_{T}$. - $\mathcal{F}_{\text {bic }}$ sends $\mathrm{msg}_{S_{1}}, \mathrm{msg}_{S_{2}}, \mathrm{msg}_{R}$ and $\mathrm{msg}_{T}$ to parties $S_{1}, S_{2}, R$ and $T$ respectively.

Figure 3.5: Functionality $\mathcal{F}_{\text {bic }}$ : Ideal Functionality for party $R$ to receive value $x$ from $S_{1}$ and $S_{2}$.

- Input: Parties $S_{1}, S_{2}, R$ and $T$ input $x, x, \mathrm{I}_{R}$ and $\mathbf{I}_{T}$ respectively.
- Output: Parties $S_{1}, S_{2}$ receive $\perp$. Parties $R$ and $T$ receive $x$ and $\perp$ as outputs respectively, when $S_{1}, S_{2}$ are honest. For the case when one among $S_{1}, S_{2}$ is corrupt, party $R$ obtains either $x$ or $\mathbf{I}_{T}$, while party $T$ obtains either $\mathrm{I}_{R}$ or $\perp$, depending on the adversary's strategy.
- Parties $S_{1}, S_{2}$ send the value $x$ to party $R$. In parallel, $S_{1}, S_{2}$ compute commitment of $x$, com $(x)$, using shared randomness known to $R$ as well (sampled from the key shared amongst $S_{1}, S_{2}$ and $R$ established during the shared key setup phase) and send it to $T$.
- If the received values match, party $R$ sets $\operatorname{msg}_{R}=$ continue, accept the value $x$ and discard any further message from $T$. Else, he sets $\operatorname{msg}_{R}=\mathrm{I}_{R}$, where $\mathrm{I}_{R}$ denotes the internal randomness of $R$.
- If the received commitments match, party $T$ sets $\operatorname{msg}_{T}=\operatorname{com}(x)$, else sets $\mathrm{msg}_{T}=\mathrm{I}_{T}$, where $\mathbf{I}_{T}$ denotes the internal randomness of $T$.
- Parties $R$ and $T$ mutually exchange the msg values.
- If $\operatorname{msg}_{R}=\mathrm{I}_{R}$ and $\operatorname{msg}_{T}=\operatorname{com}(x)$, then $R$ accepts the value $x$ that is consistent with com $(x)$.

Figure 3.6: $\Pi_{\text {bic }}\left(S_{1}, S_{2}, x, R, T\right)$ : Protocol for $S_{1}, S_{2}$ to convey a value $x$ to $R$ with the help of $T$
We now provide a brief motivation for the need of bi-convey primitive in our framework. Looking ahead, the bi-convey primitive is used as a black-box in almost all of our subsequent
protocol constructions. Consider the case where a call to this primitive from the outer protocol results in exchange of internal randomness among two parties. This implies both the parties conclude one among the remaining parties is corrupt and can safely trust each other. Thus both the honest parties combined, act as a single trusted party and use the received randomness to compute the inputs of all the parties in clear. Note that, both the honest parties together are able to compute the inputs in clear primarily because of the specific design of our mirrored sharing format (Section 3.1) where two parties together posses all the shares to reconstruct the inputs of the circuit. The honest parties then compute the final circuit output and send it to the remaining two parties ensuring guaranteed output delivery. We give a more detailed explanation of a use case of bi-convey primitive fitting in a larger protocol in Section 3.4.

Lemma 2. The designated receiver $R$ either receives a given value $x$ correctly in $\Pi_{\text {bic }}$ or receiver $R$ and helper $T$ mutually exchange all their internal randomness.

Proof. The case of $R$ and $T$ (who act as pair of honest parties) mutually exchanging their internal randomness occurs when when one of the senders $\left(S_{1}, S_{2}\right)$ are corrupt and copies of $x$ received by $R$ and the hashes $\mathrm{H}(x)$ received by $T$ mismatch. In all the other cases there always exists a majority among the copies of $x$ received by $R$. Thus $R$ is able to correctly obtain $x$ in the remaining cases.

Lemma 3. $\Pi_{\text {bic }}$ protocol requires a communication cost (amortized) of $2 \ell$ bits and at most 2 rounds.

Proof. For a given value $x$, the communication cost is equal to $2 \ell$ bits as the senders $S_{1}, S_{2}$ send $x$ to the designated party $R$. Round complexity wise, in case of a corrupt sender, he/she can delay party $R$ from receiving $x$ by at most 2 rounds. This case occurs when in the first round the copies of $x$ received by $R$ mismatch and the hashes $\mathbf{H}(x)$ received by party $T$ match. The second round simply involves party $T$ sending $\mathrm{H}(x)$ to $R$ who accepts the copy which matches with the received hash. The case when $R$ or $T$ is corrupt, $\Pi_{\text {bic }}$ will take exactly 1 round as $S_{1}$ and $S_{2}$ will always send the correct copies.

### 3.3.1 Security of Bi-Convey Primitive

In this section, we describe a detailed security proof for our Bi-Convey Primitive ( $\Pi_{\mathrm{bic}}$ ), which forms the backbone for most of our constructions, in the stand-alone model. Specifically, we prove Theorem 2 in the $\mathcal{F}_{\text {setup }}$ hybrid model.

Theorem 2. Assuming one-way functions, the protocol $\Pi_{\text {bic }}$ securely realizes the functionality $\mathcal{F}_{\text {bic }}$ in the $\mathcal{F}_{\text {setup }}$ hybrid model against one malicious corruption in the standard model.
$\mathcal{S}_{\Pi_{\text {bic }}}^{P}$ denotes the simulator for the case of a corrupt party $P \in\left\{\mathrm{~V}_{1}, \mathrm{~V}_{2}, \mathrm{E}_{1}, \mathrm{E}_{2}\right\}$. We begin with case of a corrupt $S_{1}$. Since party $S_{1}$ is not receiving any messages in the protocol $\Pi_{\mathrm{bic}}$, there is no need for $\mathcal{S}_{\Pi_{\text {bic }}}^{S_{1}}$ to simulate any messages. Based on the messages received from $S_{1}$, simulator prepares the input value of corrupt $S_{1}$ and invoke the ideal functionality $\mathcal{F}_{\text {bic }}$ (Figure 3.5). A detailed description of $\mathcal{S}_{\Pi_{\text {bic }}}^{S_{1}}$ is given in Figure 3.7. Note that, $\mathcal{S}_{\Pi_{\text {bic }}}^{S_{1}}$ has the knowledge of input value $x$, since it plays the role of an honest $S_{2}$.

1) $\mathcal{S}_{\Pi_{\text {bic }}}^{S_{1}}$ receives $x^{\prime}$ and $\operatorname{com}\left(x^{\prime \prime}\right)$ from $S_{1}$ on behalf of parties $R$ and $T$ respectively.
2) If $x^{\prime} \neq x$ or $\operatorname{com}\left(x^{\prime \prime}\right) \neq \operatorname{com}(x),{\mathcal{\Pi _ { \mathrm { H } } ^ { \mathrm { bic } }}}_{S_{1}}^{S_{1}}$ sets the input message of $S_{1}$ as $x_{S_{1}}=\perp$. Else it sets $x_{S_{1}}=x$.
3) $\mathcal{S}_{\Pi_{\text {bic }}}^{S_{1}}$ invokes the ideal functionality $\mathcal{F}_{\text {bic }}$ on behalf of $S_{1}$ with input $x_{S_{1}}$.

Figure 3.7: $\mathcal{S}_{\Pi_{\text {bic }}}^{S_{1}}$ : Simulator for the case of corrupt $S_{1}$
It is easy to see that the view of the adversary $\mathcal{A}$ in the real and simulated worlds are indistinguishable. The case for a corrupt $S_{2}$ follows similarly.

For the case of a corrupt $R, \mathcal{S}_{\Pi_{\text {bic }}}^{R}$ (Figure 3.8) samples a random $x$ on behalf of $S_{1}, S_{2}$ and prepares the commitment of $x$ honestly. This is followed by sending the values $x, x$ and $\operatorname{com}(x)$ to $R$ on behalf of $S_{1}, S_{2}$ and $T$.

1) $\mathcal{S}_{\Pi_{\text {bic }}}^{R}$ samples a random value $x$ on behalf of $S_{1}, S_{2}$. It then prepares the commitment com $(x)$ using a randomness shared with $R$.
2) $\mathcal{S}_{\Pi_{\text {bic }}}^{R}$ sends $x, x$ and $\operatorname{com}(x)$ to $R$ on behalf of $S_{1}, S_{2}$ and $T$ respectively.
3) $\mathcal{S}_{\Pi_{\text {bic }}}^{R}$ invokes the simulator for ideal functionality $\mathcal{F}_{\text {setup }}$ and obtains the internal randomness of $R, \mathbf{I}_{R}$. $\mathcal{S}_{\Pi_{\text {bic }}}^{R}$ invokes the ideal functionality $\mathcal{F}_{\text {bic }}$ on behalf of $R$ with $\mathrm{I}_{R}$ as the input.

Figure 3.8: $\mathcal{S}_{\Pi_{\mathrm{bic}}}^{R}$ : Simulator for the case of corrupt $R$
For the case of a corrupt $T, \mathcal{S}_{\Pi_{\text {bic }}}^{T}$ (Figure 3.9) proceeds as follows: $\mathcal{S}_{\Pi_{\text {bic }}}^{T}$ samples a random value $x$ on behalf of $S_{1}, S_{2}$ and prepares the commitment of $x$ honestly. This is followed by sending the values com $(x), \operatorname{com}(x)$ and $\perp$ to $T$ on behalf of $S_{1}, S_{2}$ and $R$ respectively.

1) $\mathcal{S}_{\Pi_{\text {bic }}}^{T}$ samples a random value $x$ on behalf of $S_{1}, S_{2}$. It then prepares the commitment com $(x)$.
2) $\mathcal{S}_{\Pi_{\text {bic }}}^{T}$ sends $\operatorname{com}(x), \operatorname{com}(x)$ and continue to $T$ on behalf of $S_{1}, S_{2}$ and $R$ respectively.
3) $\mathcal{S}_{\Pi_{\text {bic }}}^{T}$ invokes the simulator for ideal functionality $\mathcal{F}_{\text {setup }}$ and obtains the internal randomness of $T, \mathbf{I}_{T}$. $\mathcal{S}_{\Pi_{\text {bic }}}^{T}$ invokes the ideal functionality $\mathcal{F}_{\text {bic }}$ on behalf of $T$ with $\mathbf{I}_{T}$ as the input.

Figure 3.9: $\mathcal{S}_{\Pi_{\text {bic }}}^{T}:$ Simulator for the case of corrupt $T$

In each of the cases, since the simulator behaves entirely as an honest party in the protocol simulation, the view of the adversary $\mathcal{A}$ in the real and simulated worlds are indistinguishable in a very straightforward manner. This concludes the proof.

### 3.4 Circuit Evaluation

The circuit is evaluated in topological order where for every gate $g$ the following invariant is maintained: given the $\llbracket \cdot \rrbracket$-sharing of the inputs, the output is generated in the $\llbracket \cdot \rrbracket$-shared format. When g is an addition gate $(\mathrm{z}=\mathrm{x}+\mathrm{y})$, the linearity of $\llbracket \cdot \rrbracket$-sharing suffices to maintain this invariant.

For a multiplication gate $\mathrm{g}(\mathrm{z}=\mathrm{xy})$, the goal is for the evaluators to robustly compute $\mu_{\mathrm{z}}$ where

$$
\begin{aligned}
\mu_{\mathrm{z}} & =\mathrm{xy}+\sigma_{\mathrm{z}}=\left(\mu_{\mathrm{x}}-\sigma_{\mathrm{x}}\right)\left(\mu_{\mathrm{y}}-\sigma_{\mathrm{y}}\right)+\sigma_{\mathrm{z}} \\
& =\mu_{\mathrm{x}} \mu_{\mathrm{y}}-\mu_{\mathrm{x}} \sigma_{\mathrm{y}}-\mu_{\mathrm{y}} \sigma_{\mathrm{x}}+\sigma_{\mathrm{x}} \sigma_{\mathrm{y}}+\sigma_{\mathrm{z}}
\end{aligned}
$$

followed by evaluators setting $\mu_{z}^{2}$ share and robustly sending it to $\mathrm{V}_{2}$. On a high level, we view the aforementioned equation of $\mu_{z}$ as: $\mu_{z}=\mu_{x} \mu_{\mathrm{y}}+\mathrm{A}+\mathrm{B}$, where $\mathrm{A}=-\mu_{\mathrm{x}}^{1} \sigma_{\mathrm{y}}-\mu_{\mathrm{y}}^{1} \sigma_{\mathrm{x}}+\delta_{\mathrm{xy}}+\sigma_{\mathrm{z}}+\Delta$ is solely possessed by $\mathrm{V}_{1}$ and $\mathrm{B}=-\mu_{\mathrm{x}}^{2} \sigma_{\mathrm{y}}-\mu_{\mathrm{y}}^{2} \sigma_{\mathrm{x}}-\Delta$ is possessed $\mathrm{V}_{2}$. In order for evaluators to compute $\mu_{z}, \mathrm{E}_{1}$ and $\mathrm{E}_{2}$ needs to robustly receive $\mathrm{A}+\mathrm{B}$. Note that $\mu_{x} \mu_{y}$ is already available with the evaluators. Thus $A$ is further split into $A_{1}+A_{2}$, such that each $A_{j} \in\{1,2\}$ is possessed by $V_{1}$ and $\mathrm{E}_{j}$. Similarly, B is split such that each $\mathrm{B}_{j} \in\{1,2\}$ is possessed by $\mathrm{V}_{2}$ and $\mathrm{E}_{j}$. Now parties need to simply invoke $\Pi_{\text {bic }}$ protocol, one for each $A_{j}$ and $B_{j}$ with the co-evaluator acting as the receiving party. Thus evaluators are able to compute $\mathbf{A}+\mathrm{B}$ correctly. After computing $\mu_{\mathrm{z}}$, the evaluators set $\mu_{\mathrm{z}}^{2}=\mu_{\mathrm{z}}-\mu_{\mathrm{z}}^{1}$ and call $\Pi_{\mathrm{bic}}$ protocol to send $\mu_{\mathrm{z}}^{2}$ to $\bigvee_{2}$, where $\mu_{\mathrm{z}}^{1}$ is collectively sampled by parties in $\mathbf{E}$ and $\bigvee_{1}$. We provide the formal details of our $\Pi_{\text {mult }}(x, y, z)$ and the corresponding ideal functionality $\mathcal{F}_{\text {mul }}$ in Fig 3.11 and Fig 3.15 respectively.

Functionality $\mathcal{F}_{\text {mul }}$ receives the inputs from the parties as follows:
$-\mathrm{V}_{1}: \llbracket x \rrbracket \mathrm{~V}_{1}, \llbracket y \rrbracket \mathrm{~V}_{1}$ and internal randomness $\mathrm{I}_{\mathrm{V}_{1}}$.
$-\mathrm{V}_{2}: \llbracket x \rrbracket \mathrm{~V}_{2}, \llbracket y \rrbracket \mathrm{~V}_{2}$ and internal randomness $\mathrm{I}_{\mathrm{V}_{2}}$.
$-\mathrm{E}_{1}: \llbracket x \rrbracket_{\mathrm{E}_{1}}, \llbracket y \rrbracket_{\mathrm{E}_{1}}$ and internal randomness $\mathbf{I}_{\mathrm{E}_{1}}$.
$-\mathrm{E}_{2}: \llbracket x \rrbracket_{\mathrm{E}_{2}}, \llbracket y \rrbracket_{\mathrm{E}_{2}}$ and internal randomness $\mathbf{I}_{\mathbf{E}_{2}}$.

On receiving the inputs $\mathcal{F}_{\text {mul }}$ performs the following steps:
$-\mathcal{F}_{\text {mul }}$ sets flag $=1$, if the copies $\sigma_{x}^{1}$ received from $\mathrm{V}_{1}, \mathrm{~V}_{2}$ and $\mathrm{E}_{1}$ mismatch. $\mathcal{F}_{\text {mul }}$ also performs
similar checks for $\sigma_{x}^{2}, \mu_{x}^{1}, \mu_{x}^{2}$ and the shares of $\llbracket y \rrbracket$.

- If flag = 1 :
- $\mathcal{F}_{\text {mul }}$ uses the internal randomness of the parties, computes all the inputs $i_{1}, \ldots, i_{n}$ of the circuit in clear.
- $\mathcal{F}_{\text {mul }}$ computes $O=f\left(i_{1}, \ldots, i_{n}\right)$ locally, where $O$ denotes the output of the entire circuit evaluation.
- $\mathcal{F}_{\text {mul }}$ sends the final output $O$ to all the parties.
- Else If flag $=0$ :
- $\mathcal{F}_{\text {mul }}$ computes $x=\mu_{x}^{1}+\mu_{x}^{2}-\sigma_{x}^{1}-\sigma_{x}^{2}, y=\mu_{y}^{1}+\mu_{y}^{2}-\sigma_{y}^{1}-\sigma_{y}^{2}$ and sets $z=x y$.
- $\mathcal{F}_{\text {mul }}$ randomly samples $\sigma_{z}^{1}, \sigma_{z}^{2}$ and $\mu_{z}^{1} \in \mathbb{Z}_{2^{\ell}}$ and sets $\mu_{z}^{2}=z+\sigma_{z}^{1}+\sigma_{z}^{2}-\mu_{z}^{1}$.
- The output shares sent by $\mathcal{F}_{\text {mul }}$ are as follows:

$$
\begin{aligned}
& \mathrm{V}_{1}:\left(\sigma_{z}^{1}, \sigma_{z}^{2}, \mu_{z}^{1}\right), \mathrm{V}_{2}:\left(\sigma_{z}^{1}, \sigma_{z}^{2}, \mu_{z}^{2}\right) \\
& \mathrm{E}_{1}:\left(\sigma_{z}^{1}, \mu_{z}^{1}, \mu_{z}^{2}\right), \mathrm{E}_{2}:\left(\sigma_{z}^{2}, \mu_{z}^{1}, \mu_{z}^{2}\right)
\end{aligned}
$$

Figure 3.10: $\mathcal{F}_{\text {mul }}$ : Ideal Functionality for multiplication of $x$ and $y$

- Input: Parties input their $\llbracket x \rrbracket$ and $\llbracket y \rrbracket$ shares.
- Output: Parties obtain $\llbracket z \rrbracket$ as the output, where $z=x y$.
- Parties in $\mathbf{V}$ and $\mathbf{E}_{1}$ collectively sample $\sigma_{\mathbf{z}}^{1}$ and $\delta_{\mathrm{xy}}^{1}$, while parties in $\mathbf{V}$ and $\mathrm{E}_{2}$ together sample $\sigma_{\mathrm{z}}^{2}$.
- Verifiers $\mathrm{V}_{1}, \mathrm{~V}_{2}$ compute $\delta_{\mathrm{xy}}=\sigma_{\mathrm{x}} \sigma_{\mathrm{y}}$, set $\delta_{\mathrm{xy}}^{2}=\delta_{\mathrm{xy}}-\delta_{\mathrm{xy}}^{1}$ and invoke
$\Pi_{\mathrm{bic}}\left(\mathrm{V}_{1}, \mathrm{~V}_{2}, \delta_{\mathrm{xy}}^{2}, \mathrm{E}_{2}, \mathrm{E}_{1}\right)$, which makes sure that $\mathrm{E}_{2}$ receives $\delta_{\mathrm{xy}}^{2}$.
- Parties in $\mathbf{V}$ and $\mathrm{E}_{1}$ collectively sample $\Delta_{1}$. Parties $\mathrm{V}_{1}$ and $\mathrm{E}_{1}$ compute
$\mathrm{A}_{1}=-\mu_{\mathrm{x}}^{1} \sigma_{\mathrm{y}}^{1}-\mu_{\mathrm{y}}^{1} \sigma_{\mathrm{x}}^{1}+\delta_{\mathrm{xy}}^{1}+\sigma_{\mathrm{z}}^{1}+\Delta_{1}$ and invoke $\Pi_{\mathrm{bic}}\left(\mathrm{V}_{1}, \mathrm{E}_{1}, \mathrm{~A}_{1}, \mathrm{E}_{2}, \mathrm{~V}_{2}\right)$, such that $\mathrm{E}_{2}$ receives $\mathrm{A}_{1}$.
- Similarly, parties in $\mathbf{V}$ and $\mathrm{E}_{2}$ collectively sample $\Delta_{2}$. Parties $\mathrm{V}_{1}$ and $\mathrm{E}_{2}$ compute
$\mathrm{A}_{2}=-\mu_{\mathrm{x}}^{1} \sigma_{\mathrm{y}}^{2}-\mu_{\mathrm{y}}^{1} \sigma_{\mathrm{x}}^{2}+\delta_{\mathrm{xy}}^{2}+\sigma_{\mathrm{z}}^{2}+\Delta_{2}$ and invoke $\Pi_{\mathrm{bic}}\left(\mathrm{V}_{1}, \mathrm{E}_{2}, \mathrm{~A}_{2}, \mathrm{E}_{1}, \mathrm{~V}_{2}\right)$, such that $\mathrm{E}_{1}$ receives $\mathrm{A}_{2}$.
- Parties $\mathrm{V}_{2}$ and $\mathrm{E}_{1}$ compute $\mathrm{B}_{1}=-\mu_{\mathrm{x}}^{2} \sigma_{\mathrm{y}}^{1}-\mu_{\mathrm{y}}^{2} \sigma_{\mathrm{x}}^{1}-\Delta_{1}$ and invoke
$\Pi_{\mathrm{bic}}\left(\mathrm{V}_{2}, \mathrm{E}_{1}, \mathrm{~B}_{1}, \mathrm{E}_{2}, \mathrm{~V}_{1}\right)$. Similarly, $\mathrm{V}_{2}$ and $\mathrm{E}_{2}$ compute $\mathrm{B}_{2}=-\mu_{\mathrm{x}}^{2} \sigma_{\mathrm{y}}^{2}-\mu_{\mathrm{y}}^{2} \sigma_{\mathrm{x}}^{2}-\Delta_{2}$ and invoke $\Pi_{\mathrm{bic}}\left(\mathrm{V}_{2}, \mathrm{E}_{2}, \mathrm{~B}_{2}, \mathrm{E}_{1}, \mathrm{~V}_{1}\right)$.
- Evaluators compute $\mu_{z}=\mathrm{A}_{1}+\mathrm{A}_{2}+\mathrm{B}_{1}+\mathrm{B}_{2}+\mu_{x} \mu_{y}$ locally. Parties in $\mathbf{E}$ and $\mathrm{V}_{1}$ collectively sample $\mu_{z}^{1}$ followed by evaluators setting $\mu_{z}^{2}=\mu_{z}-\mu_{z}^{1}$ and invoking $\Pi_{\mathrm{bic}}\left(\mathrm{E}_{1}, \mathrm{E}_{2}, \mu_{z}^{2}, \mathrm{~V}_{2}, \mathrm{~V}_{1}\right)$ for $V_{2}$ to receive $\mu_{z}^{2}$.

Figure 3.11: $\Pi_{\text {mult }}(\mathrm{x}, \mathrm{y}, \mathrm{z})$ : Multiplication Protocol
For correctness of $\mu_{z}$,

$$
\begin{aligned}
\mu_{\mathrm{z}}= & \mathrm{xy}+\sigma_{\mathrm{z}}=\left(\mu_{\mathrm{x}}-\sigma_{\mathrm{x}}\right)\left(\mu_{\mathrm{y}}-\sigma_{\mathrm{y}}\right)+\sigma_{\mathrm{z}} \\
= & \mu_{\mathrm{x}} \mu_{\mathrm{y}}-\mu_{\mathrm{x}} \sigma_{\mathrm{y}}-\mu_{\mathrm{y}} \sigma_{\mathrm{x}}+\sigma_{\mathrm{x}} \sigma_{\mathrm{y}}+\sigma_{\mathrm{z}} \\
= & \left(-\mu_{\mathrm{x}}^{1} \sigma_{\mathrm{y}}-\mu_{\mathrm{y}}^{1} \sigma_{\mathrm{x}}+\delta_{\mathrm{x}}^{1}+\sigma_{\mathrm{z}}^{1}+\Delta_{1}+\Delta_{2}\right) \\
& +\left(-\mu_{\mathrm{x}}^{2} \sigma_{\mathrm{y}}-\mu_{\mathrm{y}}^{2} \sigma_{\mathrm{x}}+\delta_{\mathrm{xy}}^{2}+\sigma_{\mathrm{z}}^{2}-\Delta_{1}-\Delta_{2}\right) \\
= & \mu_{\mathrm{x}} \mu_{\mathrm{y}}+\left(\mathrm{A}_{1}+\mathrm{A}_{2}\right)+\left(\mathrm{B}_{1}+\mathrm{B}_{2}\right)
\end{aligned}
$$

where $\mathrm{A}_{j}=-\mu_{\mathrm{x}}^{1} \sigma_{\mathrm{y}}^{j}-\mu_{\mathrm{y}}^{1} \sigma_{\mathrm{x}}^{j}+\delta_{\mathrm{xy}}^{j}+\sigma_{\mathrm{z}}^{j}+\Delta_{j}$ and $\mathrm{B}_{j}=-\mu_{\mathrm{x}}^{2} \sigma_{\mathrm{y}}^{j}-\mu_{\mathrm{y}}^{2} \sigma_{\mathrm{x}}^{j}-\Delta_{j}$ for $j \in\{1,2\}$. The evaluators receive $A_{1}, A_{2}, B_{1}$ and $B_{2}$, whose correctness is guaranteed by $\Pi_{\text {bic }}$ protocol. Thus the evaluators can correctly compute $\mu_{\mathrm{z}}=\mu_{\mathrm{x}} \mu_{\mathrm{y}}+\left(\mathrm{A}_{1}+\mathrm{A}_{2}\right)+\left(\mathrm{B}_{1}+\mathrm{B}_{2}\right)$. Verifier $\mathrm{V}_{2}$ also correctly receives $\mu_{z}^{2}$ share from the evaluators, by the underlying correctness guarantee of $\Pi_{\mathrm{bic}}$ protocol.

We now analyze how $\Pi_{\text {bic }}$ primitive fits into the larger $\Pi_{\text {mult }}$ protocol to make it robust. Consider Step 2 of the protocol $\Pi_{\text {mult }}$ where parties invoke $\Pi_{\mathrm{bic}}\left(\mathrm{V}_{1}, \mathrm{~V}_{2}, \delta_{\mathrm{xy}}^{2}, \mathrm{E}_{2}, \mathrm{E}_{1}\right)$. As mentioned in Section 3.3, primitive $\Pi_{\text {bic }}$ guarantees that either i) party $\mathrm{E}_{2}$ receives the correct value $\delta_{\mathrm{xy}}^{2}$ or ii) both $E_{1}$ and $E_{2}$ identify that one among $\left(V_{1}, V_{2}\right)$ is corrupt. In the first case, parties can proceed with the execution of the protocol. For the second case, parties $\mathrm{E}_{1}$ and $\mathrm{E}_{2}$ mutually exchange their internal randomness (this includes the keys established during the shared key setup phase). Using the received randomness, both $\mathrm{E}_{1}$ and $\mathrm{E}_{2}$ can compute the missing part of her share corresponding to the $\llbracket \cdot \rrbracket$-sharing of the inputs and hence obtain all the inputs in clear. Given the inputs in clear, both $\mathrm{E}_{1}$ and $\mathrm{E}_{2}$ can compute the function output in clear and send it to the remaining two parties.

Lemma 4. For a gate $\mathrm{g}=(\mathrm{x}, \mathrm{y}, \mathrm{z})$, given the $\llbracket \cdot \rrbracket$-shares of inputs x and y , protocols $\Pi_{\text {add }}$ and $\Pi_{\text {mult }}$ compute $\llbracket \cdot \rrbracket$-share of the output wire z .

Proof. By linearity property of $\llbracket \cdot \rrbracket$-sharing, the addition gates preserve the $\llbracket \cdot \rrbracket$-sharing of their inputs. For every multiplication gate $\mathrm{g}=(\mathrm{z}=\mathrm{xy})$, the evaluators robustly compute $\mu_{z}$, after which they set $\mu_{z}^{2}=\mu_{z}-\mu_{z}^{1}\left(\mu_{z}^{1}\right.$ chosen non-interactively) for consistent $\llbracket \cdot \rrbracket$-sharing of $z$ to preserve the invariant. The share $\mu_{z}^{2}$ for every multiplication gate is later robustly communicated to the verifier $\mathrm{V}_{2}$ to maintain a consistent $\llbracket \cdot \rrbracket$-sharing for the entire circuit.

Lemma 5. $\Pi_{\text {mult }}$ protocol requires a communication cost (amortized) of $12 \ell$ bits and at most 5 rounds.

Proof. $\Pi_{\text {bic }}$ of $\delta_{x y}^{2}, \mathrm{~A}_{1}, \mathrm{~A}_{2}, \mathrm{~B}_{1}$ and $\mathrm{B}_{2}$ takes $10 \ell$ bits followed by $\Pi_{\text {bic }}$ of $\mu_{z}^{2}$ takes another $2 \ell$ bits. Round complexity wise, in case of a corrupt verifier, $\Pi_{\text {bic }}$ of $\delta_{x y}^{2}$ takes at most 2 rounds. $\Pi_{\text {bic }}$ of $A_{1}, A_{2}, B_{1}$ and $B_{2}$ also takes at most 2 rounds followed by evaluators executing $\Pi_{\text {bic }}$ of $\mu_{z}^{2}$ consumes 1 round. A similar argument can be made when one of the evaluator is corrupt.

Lemma 6. The protocol $\Pi_{4 \mathrm{PC}}$ is correct.
Proof. We argue that the computed $z$ corresponds to unique set of inputs. By Lemma 1, a corrupt party either commits to its input in which case, we proceed to evaluation or is identified to be corrupt and eliminated in which case, the output is computed on default input of the corrupt party. In the evaluation step, the computation of addition gates is local by the linearity property. For a multiplication gate $\Pi_{\text {mult }}(\mathrm{x}, \mathrm{y}, \mathrm{z})$, the correctness of $\mathrm{A}_{1}, \mathrm{~A}_{2}, \mathrm{~B}_{1}, \mathrm{~B}_{2}$ and $\delta_{x y}^{2}$ sharing follows from the correctness of $\Pi_{\text {bic }}$ protocol. Hence evaluators correctly compute $\mu_{z}$, and set $\mu_{z}^{2}=\mu_{z}-\mu_{z}^{1}$. Verifier $\bigvee_{2}$ also correctly receives $\mu_{z}^{2}$, from the underlying correctness of $\Pi_{\text {bic }}$ protocol. The protocol $\Pi_{4 \mathrm{PC}}$, relies on the the routines $\Pi_{\mathrm{sh}}, \Pi_{\text {mult }}$ and $\Pi_{\mathrm{oc}}$ and thus its correctness follows from their correctness.

### 3.4.1 Security of Multiplication

In this section, we describe a detailed security proof for our $\Pi_{\text {mult }}$ and prove security in the standard model. Specifically, we prove Theorem 3 in the $\mathcal{F}_{\text {setup }}$ hybrid model.

Theorem 3. Assuming one-way functions, the protocol $\Pi_{\text {mult }}$ securely realizes the functionality $\mathcal{F}_{\text {mul }}$ in the $\mathcal{F}_{\text {setup }}$ hybrid model against one malicious corruption in the standard model.

We first begin by describing the simulator for the case of a corrupt $V_{1}$. Note that, $\mathcal{S}_{\Pi_{\text {mult }}}^{V_{1}}$ already has the knowledge of $\mathrm{I}_{\mathrm{V}_{1}}, \delta_{\mathrm{xy}}^{2}, \mathrm{~A}_{1}$ and $\mathrm{A}_{2}$. Without loss of generality, we observe that only for the case of when $V_{1}$ acts as a sender in the $\Pi_{\text {bic }}$ protocol, the output of $\Pi_{\text {bic }}$ can lead to pair of honest parties exchanging their internal randomness with each other. Thus $\mathcal{S}_{\Pi_{\text {mult }}}^{V_{1}}$ emulates the $\mathcal{F}_{\text {bic }}$ functionality on behalf of $\mathrm{V}_{1}$ for each of $\delta_{\mathrm{xy}}^{2}, \mathrm{~A}_{1}$ and $\mathrm{A}_{2}$. The simulator then checks if any of the output leads to exchange of internal randomness among two pair of honest parties, in which case $\mathcal{S}_{\Pi_{\text {mult }}}^{\vee_{1}}$ sets $\llbracket x \rrbracket \mathrm{~V}_{1}=(\perp, \perp, \perp)$ and $\llbracket \mathrm{y} \rrbracket \mathrm{V}_{1}=(\perp, \perp, \perp)$ and invokes the $\mathcal{F}_{\text {mul }}$ functionality on behalf of $\bigvee_{1}$. This will ensure that $\mathcal{F}_{\text {mul }}$, on receiving the inputs, will find a mismatch in the copies of shares received and will directly compute the output of the entire circuit. A similar strategy is used in other simulation proofs.

1) $\mathcal{S}_{\Pi_{\text {mult }}}^{\vee_{1}}$ emulates $\mathcal{F}_{\text {bic }}$ on behalf of $\mathrm{V}_{1}$ acting as the sender, for $\delta_{x y}^{2}$. If the internal flag variable of $\mathcal{F}_{\text {bic }}$ set to 1 , simulator $\mathcal{S}_{\Pi_{\text {mutt }}}^{\vee_{1}}$ sets flag $=1$ and goes to step 3). Similar steps are followed for the case of $\mathrm{A}_{1}$ and $\mathrm{A}_{2}$.
2) If flag $=0$ :

- $\mathcal{S}_{\Pi_{\text {mult }}}^{\mathfrak{V}_{1}}$ emulates $\mathcal{F}_{\text {bic }}$ on behalf of $\mathrm{V}_{1}$ acting as the helper $T$. The simulator also invokes $\mathcal{F}_{\text {mul }}$ on behalf of $\mathrm{V}_{1}$, with inputs as $\llbracket x \mathbb{V}_{1}, \llbracket y \rrbracket_{\mathrm{V}_{1}}$ and $\mathrm{I}_{\mathrm{V}_{1}}$.

3) Else If flag $=1$ :

- $\mathcal{S}_{\Pi_{\text {mult }}}^{\mathrm{V}_{1}}$ sets $\llbracket \mathrm{x} \rrbracket \mathrm{v}_{1}=(\perp, \perp, \perp), \llbracket \mathrm{y} \rrbracket \mathrm{v}_{1}=(\perp, \perp, \perp)$ and invokes the ideal functionality $\mathcal{F}_{\text {mul }}$ on behalf of $\mathrm{V}_{1}$.
$-\mathcal{S}_{\Pi_{\text {mult }}}^{\mathrm{V}_{1}}$ sends the final circuit output $O$ to $\bigvee_{1}$ on behalf of the pair of honest parties and discards any incoming message from $\mathrm{V}_{1}$.

Figure 3.12: $\mathcal{S}_{\Pi_{\text {mult }}}^{\vee_{1}}$ : Simulator for the case of corrupt $\mathrm{V}_{1}$
This completes the simulation for the case of a corrupt $\mathrm{V}_{1}$. We now describe the simulator for the case of a corrupt $\mathrm{V}_{2}$. Simulator $\mathcal{S}_{\Pi_{\text {mult }}}^{\vee_{2}}$ already has knowledge of $\delta_{\mathrm{xy}}^{2}, \mathrm{~B}_{1}$ and $\mathrm{B}_{2}$.

1) $\mathcal{S}_{\Pi_{\text {mult }}}^{\bigvee_{2}}$ emulates $\mathcal{F}_{\text {bic }}$ on behalf of $\bigvee_{2}$ acting as the sender, for $\delta_{x y}^{2}$. If the internal flag variable of $\mathcal{F}_{\text {bic }}$ set to 1 , simulator $\mathcal{S}_{\Pi_{\text {mult }}}^{\vee_{2}}$ sets flag $=1$ and goes to step 3). Similar steps are followed for the case of $B_{1}$ and $B_{2}$.
2) If flag $=0$ :
$-\mathcal{S}_{\Pi_{\text {mult }}}^{\vee_{2}}$ emulates $\mathcal{F}_{\text {bic }}$ on behalf of $\bigvee_{2}$ acting as the receiver $R$. The simulator also invokes the ideal functionality $\mathcal{F}_{\text {mul }}$ on behalf of $\mathrm{V}_{2}$, with inputs as $\llbracket \mathrm{x} \rrbracket \mathrm{V}_{2}, \llbracket \mathrm{y} \rrbracket \mathrm{V}_{2}$ and $\mathrm{I}_{\mathrm{V}_{2}}$.
3) Else If flag = 1 :

- $\mathcal{S}_{\Pi_{\text {mult }}}^{\vee_{2}}$ sets $\llbracket \mathrm{x} \rrbracket \mathrm{V}_{2}=(\perp, \perp, \perp), \llbracket \mathrm{y} \rrbracket \mathrm{V}_{2}=(\perp, \perp, \perp)$ and invokes the ideal functionality $\mathcal{F}_{\text {mul }}$ on behalf of $V_{2}$.
$-\mathcal{S}_{\Pi_{\text {mult }}}^{\vee_{2}}$ sends the final circuit output $O$ to $\bigvee_{2}$ on behalf of the pair of honest parties and discards any incoming message from $\mathrm{V}_{2}$.

Figure 3.13: $\mathcal{S}_{\Pi_{\text {mutt }}}^{\boldsymbol{V}_{2}}$ : Simulator for the case of corrupt $\mathrm{V}_{2}$
We describe the simulator for the case of a corrupt $E_{1}$. The case of a corrupt $E_{2}$ is similar to this case and hence can be worked out in a similar way. Note that, $\mathcal{S}_{\Pi_{\text {mult }}}^{E_{1}}$ has knowledge of $\mathrm{A}_{1}, \mathrm{~B}_{1}$ and $\mu_{\mathrm{z}}^{2}$.

1) $\mathcal{S}_{\Pi_{\text {mult }}}^{E_{1}}$ emulates $\mathcal{F}_{\text {bic }}$ on behalf of $E_{1}$ acting as the sender, for each $A_{1}$ and $B_{1}$.If the internal flag variable of $\mathcal{F}_{\text {bic }}$ set to 1 , simulator $\mathcal{S}_{\Pi_{\text {mult }}}^{\mathrm{E}_{1}}$ sets flag $=1$ and goes to step 3 ).
2) If flag $=0$ :
$-\mathcal{S}_{\Pi_{\text {mult }}}^{\mathrm{E}_{1}}$ emulates $\mathcal{F}_{\text {bic }}$ on behalf of $\mathrm{E}_{1}$, for the case of $\mu_{\mathbf{z}}^{2}$, where $\mathbf{z}=x y$.If the internal flag variable of $\mathcal{F}_{\text {bic }}$ set to 1 , simulator $\mathcal{S}_{\Pi_{\text {mult }}}^{\mathrm{E}_{1}}$ sets flag $=1$ and goes to step 3 ). Else the simulator invokes $\mathcal{F}_{\text {mul }}$, with inputs as $\llbracket \mathrm{x} \rrbracket_{\mathrm{E}_{1}}, \llbracket \mathrm{y} \rrbracket_{\mathrm{E}_{1}}$ and $\mathrm{I}_{\mathrm{E}_{1}}$.
3) Else If flag =1:

- $\mathcal{S}_{\Pi_{\text {mult }}}^{E_{1}}$ sets $\llbracket x \rrbracket_{E_{1}}=(\perp, \perp, \perp), \llbracket y \rrbracket_{E_{1}}=(\perp, \perp, \perp)$ shares and invokes $\mathcal{F}_{\text {mul }}$ on behalf of $\mathrm{E}_{1}$.
$-\delta_{\Pi_{\text {mult }}}^{\mathrm{E}_{1}}$ sends the final circuit output $O$ to $\mathrm{E}_{1}$ on behalf of the pair of honest parties and discards any incoming message from $E_{1}$.

Figure 3.14: $\mathcal{S}_{\Pi_{\text {mutt }}}^{\mathrm{E}_{1}}$ : Simulator for the case of corrupt $\mathrm{E}_{1}$

### 3.5 Output Computation

The output computation phase is comparatively simple. The missing share of the output with respect to each party is possessed by the remaining three parties. Thus two out of the three parties send the missing share and the third party sends the corresponding hash. Thus each party sets the missing share as the majority among the received values and reconstruct the output. The formal details of our robust output computation protocol $\Pi_{\mathrm{oc}}$ and its corresponding ideal functionality $\mathcal{F}_{\text {oc }}$ is given in Fig 3.16 and Fig 3.5 respectively.

- Functionality $\mathcal{F}_{\text {oc }}$ receives the inputs from the parties as follows:

$$
\mathrm{V}_{1}: \llbracket z \rrbracket \mathrm{~V}_{1}, \mathrm{~V}_{2}: \llbracket z \rrbracket \mathrm{~V}_{2}, \mathrm{E}_{1}: \llbracket z \rrbracket_{\mathrm{E}_{1}}, \mathrm{E}_{2}: \llbracket z \rrbracket_{\mathrm{E}_{2}}
$$

- On receiving the inputs $\mathcal{F}_{\text {oc }}$ computes $z=\mu_{z}^{2}+\mu_{z}^{1}-\sigma_{z}^{1}-\sigma_{z}^{2}$ and sends it to all the parties.

Figure 3.15: $\mathcal{F}_{\text {oc }}$ : Ideal Functionality for Output Reconstruction

- Input: Parties input their 【z】 shares.
- Output: Parties obtain $z$ as the output.
- For $i, j \in\{1,2\}$ and $i \neq j, \mathbf{E}_{i}$ receives $\sigma_{z}^{j}$ from parties in $\mathbf{V}$ and $\mathbf{H}\left(\sigma_{z}^{j}\right)$ from $\mathbf{E}_{j}$.
- $\mathrm{V}_{2}$ receives $\mu_{\mathrm{z}}^{1}$ from parties in $\mathbf{E}$ and $\mathbf{H}\left(\mu_{\mathrm{z}}^{1}\right)$ from $\mathrm{V}_{1}$.
- $\mathrm{V}_{1}$ receives $\mu_{\mathrm{z}}^{2}$ from parties in $\mathbf{E}$ and $\mathbf{H}\left(\mu_{\mathrm{z}}^{2}\right)$ from $\mathrm{V}_{2}$.
- Each party sets the missing share as the majority among the received values and outputs $\mathrm{z}=\mu_{\mathrm{z}}^{1}+\mu_{\mathrm{z}}^{2}-\sigma_{\mathrm{z}}^{1}-\sigma_{\mathrm{z}}^{2}$.

Figure 3.16: $\Pi_{o c}$ : Protocol for Output Reconstruction

Lemma 7. The protocol $\Pi_{\mathrm{oc}}$ is correct.
Proof. The correctness for output computation follows from the fact that each party receives 2 copies and a corresponding hash for its missing share from the remaining parties. Thus each party correctly reconstructs the output as a majority always exists.

### 3.5.1 Security of Output Computation

In this section, we provide a detailed security proof for our $\Pi_{o c}$ protocol and prove security in the standard model. Specifically, we prove Theorem 4 in the $\mathcal{F}_{\text {setup }}$ hybrid model.

Theorem 4. Assuming one-way functions, the protocol $\Pi_{\mathrm{oc}}$ securely realizes the functionality $\mathcal{F}_{\text {oc }}$ in the $\mathcal{F}_{\text {setup }}$ hybrid model against one malicious corruption in the standard model.

We describe the simulator for the case of a corrupt $\mathrm{V}_{1}$ and a corrupt $\mathrm{E}_{1}$. Other cases are similar to these and hence can be worked out in a similar way. We first consider the case of a corrupt $\mathrm{V}_{1}$.

- Send $\mu_{z}^{2}$ and $\mathbf{H}\left(\mu_{z}^{2}\right)$ to $\mathrm{V}_{1}$ on behalf of honest evaluators and honest $\mathrm{V}_{2}$ respectively.

Additionally, $\mathcal{S}_{\Pi_{\mathrm{oc}}}^{\mathrm{V}_{1}}$ also receives $\sigma_{z}^{1}, \sigma_{z}^{2}$ and $\mathrm{H}\left(\mu_{z}^{1}\right)$ from $\mathrm{V}_{1}$ on behalf of honest parties.

- Invoke $\mathcal{F}_{\text {oc }}$ with input as $\llbracket z \rrbracket \bigvee_{1}$ on behalf of $\mathrm{V}_{1}$ and obtains $z$.

Figure 3.17: $\mathcal{S}_{\Pi_{o c}}^{V_{1}}$ : Simulator for $\Pi_{o c}$ with a corrupt $V_{1}$
This completes the simulation for the case of a corrupt $\mathrm{V}_{1}$. We now describe the simulator for the case of a corrupt $E_{1}$.

- Send $\sigma_{z}^{2}$ and $\mathrm{H}\left(\sigma_{z}^{2}\right)$ to $\mathrm{V}_{1}$ on behalf of honest verifiers and honest $\mathrm{E}_{2}$ respectively. Additionally, $\mathcal{S}_{\Pi_{o c}}^{E_{1}}$ also receives $\mu_{z}^{1}, \mu_{z}^{2}$ and $\mathbf{H}\left(\sigma_{z}^{1}\right)$ from $\mathbf{E}_{1}$ on behalf of honest parties.
- Invoke $\mathcal{F}_{\text {oc }}$ with input as $\llbracket z \rrbracket_{\mathrm{E}_{1}}$ on behalf of $\mathrm{E}_{1}$ and obtains $z$.

Figure 3.18: $\mathcal{S}_{\Pi_{o c}}^{E_{1}}$ : Simulator for $\Pi_{o c}$ with a corrupt $E_{1}$

## Chapter 4

## Building Blocks

In this section, we provide constructions for our crucial building blocks necessary to achieve secure training and prediction for algorithms namely- i) Linear Regression, ii) Logistic Regression, iii) Deep Neural Network (DNN) and iv) Binarized Neural Network (BNN).

### 4.1 Arithmetic/Boolean Couple Sharing

Two parties, either $\left\{\mathrm{V}_{1}, \mathrm{~V}_{2}\right\}$ (set V ) or $\left\{\mathrm{E}_{1}, \mathrm{E}_{2}\right\}$ (set $\mathbf{E}$ ) own a common value $x$ and want to create a $\llbracket \cdot \rrbracket$ - sharing of $x$. We abstract out this procedure and define it as couple sharing of a value. The formal details of the protocol $\Pi_{c S h}$ and the corresponding functionality $\mathcal{F}_{c S h}$ are given in Fig. 4.2 and Fig 4.1 respectively.

## Case 1: $(\mathbf{S}=\mathbf{E})$

- $\mathcal{F}_{\text {csh }}$ receives $x$ from parties $\mathrm{E}_{1}$ and $\mathrm{E}_{2}$ who wants to generate $\llbracket \cdot \rrbracket$-sharing of $x$. Other parties input $\perp$ to the functionality. Each party also send its internal randomness to $\mathcal{F}_{\mathrm{CSh}}$. Functionality $\mathcal{F}_{\text {CSh }}$ sets flag $=1$, if the received copies of $x$ mismatch.
- If flag =1:
- $\mathcal{F}_{\text {cSh }}$ uses the internal randomness of the parties, computes all the inputs $i_{1}, \ldots, i_{n}$ of the circuit in clear.
- $\mathcal{F}_{\text {cSh }}$ computes $O=f\left(i_{1}, \ldots, i_{n}\right)$ locally, where $O$ denotes the output of the entire circuit evaluation.
- $\mathcal{F}_{\text {cSh }}$ sends the final output $O$ to all the parties.
- If flag $=0$ :
- $\mathcal{F}_{\text {cSh }}$ randomly samples $\mu_{x}^{1} \in \mathbb{Z}_{2^{\ell}}$ and sets $\sigma_{x}^{1}=0, \sigma_{x}^{2}=0$ and $\mu_{x}^{2}=x-\mu_{x}^{1}$.
- The output shares sent by $\mathcal{F}_{\text {cSh }}$ are as follows:

$$
\begin{array}{r}
\mathrm{V}_{1}:\left(0,0, \mu_{x}^{1}\right), \mathrm{V}_{2}:\left(0,0, \mu_{x}^{2}\right) \\
\mathrm{E}_{1}:\left(0, \mu_{x}^{1}, \mu_{x}^{2}\right), \mathrm{E}_{2}:\left(0, \mu_{x}^{1}, \mu_{x}^{2}\right)
\end{array}
$$

Case 2: $(\mathbf{S}=\mathbf{V})$

- $\mathcal{F}_{\text {cSh }}$ receives $x$ from parties $\mathrm{V}_{1}$ and $\mathrm{V}_{2}$ who wants to generate $\llbracket \cdot \rrbracket$-sharing of $x$. Other parties input $\perp$ to the functionality. Each party also send its internal randomness to $\mathcal{F}_{\text {cSh }}$. Functionality $\mathcal{F}_{\text {cSh }}$ sets flag $=1$, if the received copies of $x$ mismatch.
- If flag = 1 :
- $\mathcal{F}_{\text {cSh }}$ uses the internal randomness of the parties, computes all the inputs $i_{1}, \ldots, i_{n}$ of the circuit in clear.
- $\mathcal{F}_{\text {cSh }}$ computes $O=f\left(i_{1}, \ldots, i_{n}\right)$ locally, where $O$ denotes the output of the entire circuit evaluation.
- $\mathcal{F}_{\text {cSh }}$ sends the final output $O$ to all the parties.
- If flag $=0$ :
- $\mathcal{F}_{\text {cSh }}$ randomly samples $\sigma_{x}^{1} \in \mathbb{Z}_{2^{\ell}}$ and sets $\mu_{x}^{1}=0, \mu_{x}^{2}=0$ and $\sigma_{x}^{2}=x-\sigma_{x}^{1}$.
- The output shares sent by $\mathcal{F}_{\text {cSh }}$ are as follows:

$$
\begin{aligned}
& \mathrm{V}_{1}:\left(\sigma_{x}^{1}, \sigma_{x}^{2}, 0\right), \mathrm{V}_{2}:\left(\sigma_{x}^{1}, \sigma_{x}^{2}, 0\right) \\
& \mathrm{E}_{1}:\left(\sigma_{x}^{1}, 0,0\right), \mathrm{E}_{2}:\left(\sigma_{x}^{2}, 0,0\right)
\end{aligned}
$$

Figure 4.1: Functionality $\mathcal{F}_{\text {cSh }}$ : Ideal Functionality for Couple Sharing of $x$

## Case 1: $(\mathbf{S}=\mathrm{E})$

- Input: $\mathrm{E}_{1}$ and $\mathrm{E}_{2}$ input $x$ while others input $\perp$.
- Output: Parties obtain $\llbracket x \rrbracket$ as the output.
- Parties set $\sigma_{x}^{1}=0$ and $\sigma_{x}^{2}=0$. Parties in $\mathbf{E}$ and $\mathrm{V}_{1}$ collectively sample random $\mu_{x}^{1} \in \mathbb{Z}_{2^{\ell}}$.
$-\mathrm{E}_{1}$ and $\mathrm{E}_{2}$ set $\mu_{x}^{2}=x-\mu_{x}^{1}$. Parties then execute $\Pi_{\text {bic }}\left(\mathrm{E}_{1}, \mathrm{E}_{2}, \mu_{x}^{2}, \mathrm{~V}_{2}, \mathrm{~V}_{1}\right)$, such that $\mathrm{V}_{2}$ receives $\mu_{x}^{2}$.

Case 2: $(\mathbf{S}=\mathrm{V})$

- Input: $\mathrm{V}_{1}$ and $\mathrm{V}_{2}$ input $x$ while others input $\perp$.
- Output: Parties obtain $\llbracket x \rrbracket$ as the output.
- Parties set $\mu_{x}^{1}=0$ and $\mu_{x}^{2}=0$. Parties in $\mathbf{V}$ and $\mathbf{E}_{1}$ collectively sample random $\sigma_{x}^{1} \in \mathbb{Z}_{2^{2}}$.
$-\mathrm{V}_{1}$ and $\mathrm{V}_{2}$ set $\sigma_{x}^{2}=x-\sigma_{x}^{1}$. Parties then execute $\Pi_{\text {bic }}\left(\mathrm{V}_{1}, \mathrm{~V}_{2}, \sigma_{x}^{2}, \mathrm{E}_{2}, \mathrm{E}_{1}\right)$, such that $\mathrm{E}_{2}$ receives $\sigma_{x}^{2}$.

Figure 4.2: $\Pi_{\mathrm{cSh}}(\mathbf{S}, x)$ : Protocol to generate couple sharing of $x$
On a high level when set $\mathbf{S}=\mathbf{E}$, in order to share a value $x$, parties set $\sigma_{x}^{1}=\sigma_{x}^{2}=0$. A random $\mu_{x}^{1}$ is collectively sampled and the owners of the value set $\mu_{x}^{2}$ such that $\mu_{x}^{1}+\mu_{x}^{2}=x$ and send $\mu_{x}^{2}$ to $\mathrm{V}_{2}$ using $\Pi_{\text {bic }}$ protocol. The shares of parties can be viewed as:

$$
\begin{array}{ll}
\mathrm{E}_{1}: \llbracket x \rrbracket_{\mathrm{E}_{1}}=\left(0, \mu_{x}^{1}, \mu_{x}^{2}\right) & \mathrm{V}_{1}: \llbracket x \rrbracket_{\mathrm{V}_{1}}=\left(0,0, \mu_{x}^{1}\right) \\
\mathrm{E}_{2}: \llbracket x \rrbracket_{\mathrm{E}_{2}}=\left(0, \mu_{x}^{1}, \mu_{x}^{2}\right) & \mathrm{V}_{2}: \llbracket x \rrbracket_{\mathrm{V}_{2}}=\left(0,0, \mu_{x}^{2}\right)
\end{array}
$$

For the case when set $\mathbf{S}=\mathbf{V}$ and value $x$, parties in $\mathbf{V}$ and $\mathbf{E}_{1}$ collectively sample random $\sigma_{x}^{1}$ followed by $\mathbf{V}$ setting $\sigma_{x}^{2}=-x-\sigma_{x}^{1}$ and robustly sending it to $\mathbf{E}_{2}$. Now, the shares of parties are viewed as:

$$
\begin{array}{ll}
\mathrm{E}_{1}: \llbracket x \rrbracket_{\mathrm{E}_{1}}=\left(\sigma_{x}^{1}, 0,0\right) & \mathrm{V}_{1}: \llbracket x \rrbracket_{\mathrm{V}_{1}}=\left(\sigma_{x}^{1}, \sigma_{x}^{2}, 0\right) \\
\mathrm{E}_{2}: \llbracket x \rrbracket_{\mathrm{E}_{2}}=\left(\sigma_{x}^{2}, 0,0\right) & \mathrm{V}_{2}: \llbracket x \rrbracket_{\mathrm{V}_{2}}=\left(\sigma_{x}^{1}, \sigma_{x}^{2}, 0\right)
\end{array}
$$

Lemma 8. $\Pi_{c S h}$ protocol requires a communication cost (amortized) of $2 \ell$ bits and at most 2 rounds when parties in $\mathbf{E}$ couple share.

Proof. The communication cost of $2 \ell$ bits comes directly from the cost of $\Pi_{\text {bic }}$ protocol as the rest of the steps are local, which includes collectively sampling $\mu_{x}^{1}$. Round complexity argument also follow from $\Pi_{\text {bic }}$ protocol.

Lemma 9. $\Pi_{c S h}$ protocol requires a communication cost (amortized) of $2 \ell$ bits and at most 2 rounds when parties in $\mathbf{V}$ couple share .

Proof. The communication cost of $2 \ell$ bits comes directly from the cost of $\Pi_{\text {bic }}$ protocol as the rest of the steps are local, which includes collectively sampling $\sigma_{x}^{1}$. Round complexity argument also follow from $\Pi_{\text {bic }}$ protocol.

### 4.1.1 Security of Couple Sharing

In this section, we describe a detailed security proof for our Dot Product Protocol and prove security in the standard model. Specifically, we prove Theorem 5 in the $\mathcal{F}_{\text {setup }}$ hybrid model.

Theorem 5. Assuming one-way functions, the protocol $\Pi_{c S h}$ securely realizes the functionality $\mathcal{F}_{\text {cSh }}$ in the $\mathcal{F}_{\text {setup }}$ hybrid model against one malicious corruption in the standard model.

We first begin by describing the simulator for the case of a corrupt $\mathrm{V}_{1}$ for both the cases of $\mathbf{S}=\mathbf{E}$ and $\mathbf{V}$. In case of $\mathbf{S}=\mathbf{E}$, simulator $\mathcal{S}_{\Pi_{\mathrm{cS}}}^{\bigvee_{1}}$ emulates the $\mathcal{F}_{\text {bic }}$ functionality on behalf of $\mathrm{V}_{1}$ as the helper for $\mu_{x}^{2}$. In case of $\mathbf{S}=\mathbf{V}$, simulator $\mathcal{S}_{\Pi_{\text {cSh }}}^{\vee_{1}}$ emulates the $\mathcal{F}_{\text {bic }}$ functionality on behalf of $\mathrm{V}_{1}$ as the sender for $\sigma_{x}^{2}$. The simulator then checks if any of the output leads to exchange of internal randomness among two pair of honest parties, in which case $\mathcal{S}_{\Pi_{\mathrm{csh}}}^{V_{1}}$ sets $x=\perp$, and invokes the $\mathcal{F}_{\text {cSh }}$ functionality on behalf of $\mathrm{V}_{1}$. The case of a corrupt $\mathrm{V}_{2}$ is similar to this case and hence can be worked out in a similar way.

Case 1: $(\mathbf{S}=\mathbf{E})$

1) $\mathcal{S}_{\Pi_{\text {CSh }}}^{\vee_{1}}$ emulates $\mathcal{F}_{\text {bic }}$ on behalf of $\bigvee_{1}$ acting as the helper, for $\mu_{x}^{2}$.
2) The simulator invokes the ideal functionality $\mathcal{F}_{C S h}$ on behalf of $\mathrm{V}_{1}$, with input as $x$.

Case 2: $(\mathbf{S}=\mathbf{V})$

1) $\mathcal{S}_{\Pi_{\text {csh }}}^{\mathrm{V}_{1}}$ emulates $\mathcal{F}_{\text {bic }}$ on behalf of $\mathrm{V}_{1}$ acting as the sender, for $\sigma_{x}^{2}$. If the internal flag variable of $\mathcal{F}_{\text {bic }}$ set to 1 , simulator $\mathcal{S}_{\Pi_{\mathrm{csh}}}^{V_{1}}$ sets flag $=1$ and goes to step 3).
2) If flag $=0$ :

- The simulator invokes the ideal functionality $\mathcal{F}_{\text {cSh }}$ on behalf of $\mathrm{V}_{1}$, with input as $x$.

3) Else If flag = 1:

- The simulator invokes the ideal functionality $\mathcal{F}_{\text {cSh }}$ on behalf of $\bigvee_{1}$, with input as $\perp$.
$-\delta_{\Pi_{\text {csh }}}^{V_{1}}$ sends the final circuit output $O$ to $\mathrm{V}_{1}$ on behalf of the pair of honest parties and discards any incoming message from $\mathrm{V}_{1}$.

Figure 4.3: $\mathcal{S}_{\Pi_{c S h}}^{\vee_{1}}$ : Simulator for the case of corrupt $\mathrm{V}_{1}$
We describe the simulator for the case of a corrupt $E_{1}$. The simulation steps for a corrupt $\mathrm{E}_{2}$ is similar to this case and hence can be worked out in a similar way.

## Case 1: $(\mathbf{S}=\mathbf{E})$

1) $\mathcal{S}_{\Pi_{c S h}}^{\mathrm{E}_{1}}$ emulates $\mathcal{F}_{\text {bic }}$ on behalf of $\mathrm{E}_{1}$ acting as the sender, for $\mu_{x}^{2}$. If the internal flag variable of $\mathcal{F}_{\text {bic }}$ set to 1 , simulator $\mathcal{S}_{\Pi_{\text {cSh }}}^{V_{1}}$ sets flag $=1$ and goes to step 3 ).
2) If flag $=0$ :

- The simulator invokes the ideal functionality $\mathcal{F}_{\text {cSh }}$ on behalf of $\mathrm{E}_{1}$, with input as $x$.

3) Else If flag $=1$ :

- The simulator invokes the ideal functionality $\mathcal{F}_{\text {cSh }}$ on behalf of $\mathrm{E}_{1}$, with input as $\perp$.
$-\mathcal{S}_{\Pi_{\mathrm{cSh}}}^{\mathrm{E}_{1}}$ sends the final circuit output $O$ to $\mathrm{E}_{1}$ on behalf of the pair of honest parties and discards any incoming message from $\mathrm{E}_{1}$.

Case 2: $(\mathbf{S}=\mathrm{V})$

1) $\mathcal{S}_{\Pi_{\mathrm{cSh}}}^{\mathrm{E}_{1}}$ emulates $\mathcal{F}_{\text {bic }}$ on behalf of $\mathrm{E}_{1}$ acting as the helper, for $\sigma_{x}^{2}$.
2) The simulator invokes the ideal functionality $\mathcal{F}_{\text {cSh }}$ on behalf of $\mathrm{E}_{1}$, with input as $x$.

Figure 4.4: $\mathcal{S}_{\Pi_{c S h}}^{\mathrm{E}_{1}}$ : Simulator for the case of corrupt $\mathrm{E}_{1}$

### 4.2 Dot Product

Given vectors $\overrightarrow{\mathbf{x}}$ and $\overrightarrow{\mathbf{y}}$, each of size $d$, the goal is to compute the dot product $\mathbf{z}=\overrightarrow{\mathbf{x}} \odot \overrightarrow{\mathbf{y}}=$ $\sum_{i=1}^{d} \mathrm{x}_{i} \mathrm{y}_{i}$. The recent works of ABY3 and ASTRA have tackled dot product computation in the semi-honest setting with cost equal to that of a single multiplication thus, making the total cost independent of the vector size. However, in the malicious setting, their techniques become expensive, with cost dependent on the vector size. In this work, we remove this dependency and retain the cost to be the same as that of a single multiplication. This independence stems from the peculiar structure of our sharing and our robust multiplication method. On a high level, instead of calling $\Pi_{\text {bic }}$ protocol for $\mathrm{A}_{1 i}, \mathrm{~A}_{2 i}, \mathrm{~B}_{1 i}$ and $\mathrm{B}_{2 i}$ corresponding to each product $\mathrm{z}_{i}=\mathrm{x}_{i} \mathrm{y}_{i}$, the parties add up their shares and then invoke $\Pi_{\text {bic }}$ once for each of the summed up share. To facilitate this modification, verifiers also adjust $\delta_{\mathrm{xy}}^{2}=\sum_{i=1}^{d} \delta_{x_{i} y_{i}}-\delta_{\mathrm{xy}}^{1}$ before sending to $\mathrm{E}_{2}$. Formal details of the ideal functionality $\mathcal{F}_{\mathrm{dp}}$ and the protocol $\Pi_{\mathrm{dp}}$ are presented in Fig.4.5 and Fig.4.6 respectively.

Functionality $\mathcal{F}_{\text {dp }}$ receives the inputs from the parties as follows:
$-\mathrm{V}_{1}: \llbracket \overrightarrow{\mathrm{x}} \rrbracket \mathrm{V}_{1}, \llbracket \overrightarrow{\mathrm{y}} \rrbracket \mathrm{V}_{1}$ and internal randomness $\mathrm{I}_{\mathrm{V}_{1}}$.
$-\mathrm{V}_{2}: \llbracket \overrightarrow{\mathrm{x}} \rrbracket \mathrm{V}_{2}, \llbracket \overrightarrow{\mathrm{y}} \rrbracket_{\mathrm{V}_{2}}$ and internal randomness $\mathrm{I}_{\mathrm{V}_{2}}$.
$\left.\left.-\mathrm{E}_{1}: \llbracket \overrightarrow{\mathrm{x}}\right]_{\mathrm{E}_{1}}, \llbracket \overrightarrow{\mathrm{y}}\right]_{\mathrm{E}_{1}}$ and internal randomness $\mathrm{I}_{\mathrm{E}_{1}}$.
$-\mathrm{E}_{2}: \llbracket \overrightarrow{\mathrm{x}} \rrbracket_{\mathrm{E}_{2}}, \llbracket \overrightarrow{\mathrm{y}} \rrbracket_{\mathrm{E}_{2}}$ and internal randomness $\mathrm{I}_{\mathrm{E}_{2}}$.

On receiving the inputs $\mathcal{F}_{\text {dp }}$ performs the following steps:

- If for any $\sigma_{x_{i}}^{1} \in \sigma_{\overrightarrow{\mathbf{x}}}^{1}$, the copies of $\sigma_{x_{i}}^{1}$ received from $\mathrm{V}_{1}, \mathrm{~V}_{2}$ and $\mathrm{E}_{1}$ mismatch, $\mathcal{F}_{\text {dp }}$ sets flag $=1$. $\mathcal{F}_{\mathrm{dp}}$ also performs similar checks for $\sigma_{\overrightarrow{\mathbf{x}}}^{2}, \mu_{\overrightarrow{\mathbf{x}}}^{1}, \mu_{\overrightarrow{\mathbf{x}}}^{2}$ and the shares of $\llbracket \overrightarrow{\mathbf{y}} \rrbracket$.
- If flag = 1 :
$-\mathcal{F}_{\mathrm{dp}}$ uses the internal randomness of the parties, computes all the inputs $i_{1}, \ldots, i_{n}$ of the circuit in clear.
- $\mathcal{F}_{\mathrm{dp}}$ computes $O=f\left(i_{1}, \ldots, i_{n}\right)$ locally, where $O$ denotes the output of the entire circuit evaluation.
- $\mathcal{F}_{\mathrm{dp}}$ sends the final output $O$ to all the parties.
- Else If flag $=0$ :
- $\mathcal{F}_{\text {mul }}$ computes $\forall i, x_{i}=\mu_{x_{i}}^{1}+\mu_{x_{i}}^{2}-\sigma_{x_{i}}^{1}-\sigma_{x_{i}}^{2}, y_{i}=\mu_{y_{i}}^{1}+\mu_{y_{i}}^{2}-\sigma_{y_{i}}^{1}-\sigma_{y_{i}}^{2}$ and set $z=\Sigma_{i=1}^{d} x_{i} y_{i}$.
- $\mathcal{F}_{\text {mul }}$ randomly samples $\sigma_{z}^{1}, \sigma_{z}^{2}$ and $\mu_{z}^{1} \in \mathbb{Z}_{2^{\ell}}$ and set $\mu_{z}^{2}=z+\sigma_{z}^{1}+\sigma_{z}^{2}-\mu_{z}^{1}$.
- The output shares sent by $\mathcal{F}_{\text {mul }}$ are as follows:

$$
\begin{aligned}
& \mathrm{V}_{1}:\left(\sigma_{z}^{1}, \sigma_{z}^{2}, \mu_{z}^{1}\right), \mathrm{V}_{2}:\left(\sigma_{z}^{1}, \sigma_{z}^{2}, \mu_{z}^{2}\right) \\
& \mathrm{E}_{1}:\left(\sigma_{z}^{1}, \mu_{z}^{1}, \mu_{z}^{2}\right), \mathrm{E}_{2}:\left(\sigma_{z}^{2}, \mu_{z}^{1}, \mu_{z}^{2}\right)
\end{aligned}
$$

Figure 4.5: $\quad \mathcal{F}_{\mathrm{dp}}$ : Ideal Functionality for dot product of two values $x$ and $y$

- Input: Parties input their $\llbracket \overrightarrow{\mathbf{x}} \rrbracket$ and $\llbracket \overrightarrow{\mathbf{y}} \rrbracket$ shares.
- Output: Parties obtain $\llbracket \mathrm{z} \rrbracket$ as output, where $\mathbf{z}=\overrightarrow{\mathbf{x}} \odot \overrightarrow{\mathbf{y}}$.
- Parties in $\mathbf{V}$ and $\mathrm{E}_{1}$ collectively sample $\sigma_{\mathrm{z}}^{1}$ and $\delta_{\mathrm{xy}}^{1}$, while parties in $\mathbf{V}$ and $\mathrm{E}_{2}$ together sample $\sigma_{\mathrm{z}}^{2}$.
- Verifiers $\mathrm{V}_{1}, \mathrm{~V}_{2}$ compute $\delta_{\mathrm{xy}}=\Sigma_{i=1}^{d} \sigma_{\mathrm{x}_{i}} \sigma_{\mathrm{y}_{i}}$, set $\delta_{\mathrm{xy}}^{2}=\delta_{\mathrm{xy}}-\delta_{\mathrm{xy}}^{1}$ and invoke $\Pi_{\mathrm{bic}}\left(\mathrm{V}_{1}, \mathrm{~V}_{2}, \delta_{\mathrm{xy}}^{2}, \mathrm{E}_{2}, \mathrm{E}_{1}\right)$, such that $\mathrm{E}_{2}$ receives $\delta_{\mathrm{xy}}^{2}$.
- Parties in $\mathbf{V}$ and $\mathrm{E}_{1}$ collectively sample $\Delta_{1}$. Parties $\mathrm{V}_{1}$ and $\mathrm{E}_{1}$ compute $\mathrm{A}_{1}=\Sigma_{i=1}^{d}\left(-\mu_{x_{i}}^{1} \sigma_{y_{i}}^{1}-\right.$ $\left.\mu_{y_{i}}^{1} \sigma_{x_{i}}^{1}\right)+\sigma_{\mathrm{z}}^{1}+\delta_{\mathrm{xy}}^{1}+\Delta_{1}$ and invoke $\Pi_{\mathrm{bic}}\left(\mathrm{V}_{1}, \mathrm{E}_{1}, \mathrm{~A}_{1}, \mathrm{E}_{2}, \mathrm{~V}_{2}\right)$, such that $\mathrm{E}_{2}$ receives $\mathrm{A}_{1}$.
- Similarly, parties in $\mathbf{V}$ and $\mathrm{E}_{2}$ collectively sample $\Delta_{2}$. Parties $\mathrm{V}_{1}$ and $\mathrm{E}_{2}$ compute $\mathrm{A}_{2}=$ $\sum_{i=1}^{d}\left(-\mu_{x_{i}}^{1} \sigma_{y_{i}}^{2}-\mu_{y_{i}}^{1} \sigma_{x_{i}}^{2}\right)+\sigma_{\mathrm{z}}^{2}+\delta_{\mathrm{xy}}^{2}+\Delta_{2}$ and invoke $\Pi_{\text {bic }}\left(V_{1}, E_{2}, A_{2}, E_{1}, V_{2}\right)$, such that $E_{1}$ receives $A_{2}$.
$-\mathrm{V}_{2}$ and $\mathrm{E}_{1}$ compute $\mathrm{B}_{1}=\Sigma_{i=1}^{d}\left(-\mu_{x_{i}}^{2} \sigma_{y_{i}}^{1}-\mu_{y_{i}}^{2} \sigma_{x_{i}}^{1}\right)-\Delta_{1}$ and invoke $\Pi_{\mathrm{bic}}\left(\mathrm{V}_{2}, \mathrm{E}_{1}, \mathrm{~B}_{1}, \mathrm{E}_{2}, \mathrm{~V}_{1}\right)$. Similarly, $\mathrm{V}_{2}$ and $\mathrm{E}_{2}$ compute $\mathrm{B}_{2}=\Sigma_{i=1}^{d}\left(-\mu_{x_{i}}^{2} \sigma_{y_{i}}^{2}-\mu_{y_{i}}^{2} \sigma_{x_{i}}^{2}\right)-\Delta_{2}$ and execute $\Pi_{\mathrm{bic}}\left(\mathrm{V}_{2}, \mathrm{E}_{2}, \mathrm{~B}_{2}, \mathrm{E}_{1}, \mathrm{~V}_{1}\right)$.
- Evaluators compute $\mu_{z}=\mu_{x} \mu_{y}+\mathrm{A}_{1}+\mathrm{A}_{2}+\mathrm{B}_{1}+\mathrm{B}_{2}$ locally. Parties in $\mathbf{E}$ and $\mathrm{V}_{1}$ collectively sample $\mu_{z}^{1}$ followed by evaluators setting $\mu_{z}^{2}=\mu_{z}-\mu_{z}^{1}$ and execute $\Pi_{\mathrm{bic}}\left(\mathrm{E}_{1}, \mathrm{E}_{2}, \mu_{z}^{2}, \mathrm{~V}_{2}, \mathrm{~V}_{1}\right)$ for $\mathrm{V}_{2}$ to receive $\mu_{z}^{2}$.

Figure 4.6: $\Pi_{\mathrm{dp}}(\llbracket \overrightarrow{\mathbf{x}} \rrbracket, \llbracket \overrightarrow{\mathbf{y}} \rrbracket)$ : Dot Product of two vectors

Lemma 10. $\Pi_{\mathrm{dp}}$ protocol requires a communication cost (amortized) of $12 \ell$ bits and at most 5 rounds.

Proof. The communication cost of $12 \ell$ bits comes directly from the cost of $\Pi_{\text {mult }}$ protocol as the rest of the steps are local. Round complexity argument also follow from $\Pi_{\text {mult }}$ protocol.

### 4.2.1 Security of Dot Product

In this section, we describe a detailed security proof for our Dot Product Protocol and prove security in the standard model. Specifically, we prove Theorem 6 in the $\mathcal{F}_{\text {setup }}$ hybrid model.

Theorem 6. Assuming one-way functions, the protocol $\Pi_{\mathrm{dp}}$ securely realizes the functionality $\mathcal{F}_{\mathrm{dp}}$ in the $\mathcal{F}_{\text {setup }}$ hybrid model against one malicious corruption in the standard model.

We first begin by describing the simulator for the case of a corrupt $\bigvee_{1}$. Thus $\mathcal{S}_{\Pi_{\mathrm{dp}}}^{\bigvee_{1}}$ emulates the $\mathcal{F}_{\text {bic }}$ functionality on behalf of $\mathrm{V}_{1}$ for each of $\delta_{\text {xy }}^{2}, \mathrm{~A}_{1}$ and $\mathrm{A}_{2}$. The simulator then checks if any of the output leads to exchange of internal randomness among two pair of honest parties, in which case $\mathcal{S}_{\Pi_{\mathrm{dp}}}^{\vee_{1}}$ sets $\llbracket \overrightarrow{\mathbf{x}} \rrbracket \mathrm{V}_{1}=(\perp, \perp, \perp), \llbracket \overrightarrow{\mathbf{y}} \rrbracket \mathbb{V}_{1}=(\perp, \perp, \perp)$ and invokes the $\mathcal{F}_{\mathrm{dp}}$ functionality on behalf of $\mathrm{V}_{1}$.

1) $\mathcal{S}_{\Pi_{\mathrm{d}}}^{\vee_{1}}$ emulates $\mathcal{F}_{\text {bic }}$ on behalf of $\mathrm{V}_{1}$ acting as the sender, for $\delta_{\mathrm{xy}}^{2}$. If the internal flag variable of $\mathcal{F}_{\text {bic }}$ set to 1 , simulator $\mathcal{S}_{\Pi_{\text {dp }}}^{V_{1}}$ sets flag $=1$ and goes to step 3). Similar steps are followed for the case of $\mathrm{A}_{1}$ and $\mathrm{A}_{2}$.
2) If flag $=0$ :
$-\mathcal{S}_{\Pi_{\mathrm{dp}}}^{\vee_{1}}$ emulates $\mathcal{F}_{\text {bic }}$ on behalf of $\mathrm{V}_{1}$ acting as the helper $T$. The simulator also invokes the ideal functionality $\mathcal{F}_{\mathrm{dp}}$ on behalf of $\mathrm{V}_{1}$, with inputs as $\llbracket \overrightarrow{\mathrm{x}} \rrbracket \mathrm{V}_{1}, \llbracket \overrightarrow{\mathrm{y}} \rrbracket \mathrm{V}_{1}$ and $\mathrm{I}_{\mathrm{V}_{1}}$.
3) Else If flag = 1 :

- $\mathcal{S}_{\Pi_{\mathrm{dp}}}^{\mathrm{V}_{1}}$ sets $\llbracket \overrightarrow{\mathbf{x}} \rrbracket \mathrm{V}_{1}=(\perp, \perp, \perp), \llbracket \overrightarrow{\mathbf{y}} \rrbracket \mathrm{V}_{1}=(\perp, \perp, \perp)$ shares and invokes the ideal functionality $\mathcal{F}_{\mathrm{dp}}$ on behalf of $\mathrm{V}_{1}$.
$-\mathcal{S}_{\Pi_{\mathrm{dp}}}^{\vee_{1}}$ sends the final circuit output $O$ to $\mathrm{V}_{1}$ on behalf of the pair of honest parties and discards any incoming message from $\mathrm{V}_{1}$.

Figure 4.7: $\mathcal{S}_{\Pi_{\mathrm{dp}}}^{V_{1}}$ : Simulator for the case of corrupt $\mathrm{V}_{1}$
This completes the simulation for the case of a corrupt $\mathrm{V}_{1}$. We now describe the simulator for the case of a corrupt $\mathrm{V}_{2}$.

1) $\mathcal{S}_{\Pi_{\mathrm{dp}}}^{\bigvee_{2}}$ emulates $\mathcal{F}_{\text {bic }}$ on behalf of $\mathrm{V}_{2}$ acting as the sender, for $\delta_{\mathrm{xy}}^{2}$. If the internal flag variable of $\mathcal{F}_{\text {bic }}$ set to 1 , simulator $\mathcal{S}_{\Pi_{\mathrm{dp}}}^{V_{2}}$ sets flag $=1$ and goes to step 3). Similar steps are followed for the case of $\mathrm{B}_{1}$ and $\mathrm{B}_{2}$.
2) If flag $=0$ :

- $\mathcal{S}_{\Pi_{\mathrm{dp}}}^{\vee_{2}}$ emulates $\mathcal{F}_{\text {bic }}$ on behalf of $\mathrm{V}_{2}$ acting as the receiver $R$. The simulator also invokes the ideal functionality $\mathcal{F}_{\mathrm{dp}}$ on behalf of $\mathrm{V}_{2}$, with inputs as $\llbracket \overrightarrow{\mathbf{x}} \rrbracket \mathrm{V}_{2}$, $\llbracket \overrightarrow{\mathrm{y}} \rrbracket \mathrm{V}_{2}$ and $\mathrm{I}_{\mathrm{V}_{2}}$.

3) Else If flag = 1:

- $\mathcal{S}_{\Pi_{\mathrm{dp}}}^{\mathrm{V}_{2}}$ sets $\llbracket \overrightarrow{\mathbf{x}} \rrbracket \mathrm{V}_{2}=(\perp, \perp, \perp), \llbracket \overrightarrow{\mathbf{y}} \rrbracket \bigvee_{2}=(\perp, \perp, \perp)$ shares and invokes the ideal functionality $\mathcal{F}_{\mathrm{dp}}$ on behalf of $\mathrm{V}_{2}$.
$-\mathcal{S}_{\Pi_{\mathrm{dp}}}^{\mathrm{V}_{2}}$ sends the final circuit output $O$ to $\mathrm{V}_{2}$ on behalf of the pair of honest parties and discards any incoming message from $V_{2}$.

Figure 4.8: $\mathcal{S}_{\Pi_{\mathrm{dp}}}^{V_{2}}$ : Simulator for the case of corrupt $\mathrm{V}_{2}$
We describe the simulator for the case of a corrupt $E_{1}$. The case of a corrupt $E_{2}$ is similar to this case and hence can be worked out in a similar way.

1) $\mathcal{S}_{\Pi_{\text {dp }}}^{E_{1}}$ emulates $\mathcal{F}_{\text {bic }}$ on behalf of $E_{1}$ acting as the sender, for each $A_{1}$ and $B_{1}$.If the internal flag variable of $\mathcal{F}_{\text {bic }}$ set to 1 , simulator $\mathcal{S}_{\Pi_{\text {dp }}}^{\mathrm{E}_{1}}$ sets flag $=1$ and goes to step 3).
2) If flag $=0$ :
$-\mathcal{S}_{\Pi_{\mathrm{dp}}}^{\mathrm{E}_{1}}$ emulates $\mathcal{F}_{\text {bic }}$ on behalf of $\mathrm{E}_{1}$, for the case of $\mu_{\mathrm{z}}^{2}$, where $\mathbf{z}=\sum_{i=1}^{d} x_{i} y_{i}$. If the internal flag variable of $\mathcal{F}_{\text {bic }}$ set to 1 , simulator $\mathcal{S}_{\Pi_{\text {dp }}}^{E_{1}}$ sets flag' $=1$ and goes to step 3 ). Else the simulator invokes $\mathcal{F}_{\text {dp }}$, with inputs as $\llbracket \overrightarrow{\mathbf{x}} \rrbracket_{E_{1}}, \llbracket \overrightarrow{\mathbf{y}} \rrbracket_{\mathrm{E}_{1}}$ and $\mathrm{I}_{\mathrm{E}_{1}}$.
3) Else If flag = 1:
$-\mathcal{S}_{\Pi_{\mathrm{dp}}}^{\mathrm{E}_{1}}$ sets $\llbracket \overrightarrow{\mathbf{x}} \rrbracket_{\mathrm{E}_{1}}=(\perp, \perp, \perp), \llbracket \overrightarrow{\mathbf{y}} \rrbracket_{\mathrm{E}_{1}}=(\perp, \perp, \perp)$ shares and invokes $\mathcal{F}_{\mathrm{dp}}$ on behalf of $\mathrm{E}_{1}$.
$-\delta_{\Pi_{\mathrm{dp}}}^{\mathrm{E}_{1}}$ sends the final circuit output $O$ to $\mathrm{E}_{1}$ on behalf of the pair of honest parties and discards any incoming message from $E_{1}$.

Figure 4.9: $\mathcal{S}_{\Pi_{\mathrm{dp}}}^{E_{1}}$ : Simulator for the case of corrupt $\mathrm{E}_{1}$

### 4.3 MSB Extraction

All machine learning models which perform the task of classification require comparison between two values as a building block during their process of training and prediction. Efficient comparison of two arithmetic values $u$ and $v$ in a private fashion has been an ongoing challenging problem. Concretely, given the arithmetic shares $\llbracket u \rrbracket$ and $\llbracket v \rrbracket$, the goal is to check if $u<v$.

In fixed point arithmetic setting, we check $\operatorname{msb}(a)=1$, if $a=v-u<0$ and vice-versa. Thus the goal of the parties reduces to computing the $\llbracket \cdot \rrbracket^{\mathrm{B}}$ shares of msb(a) given the $\llbracket \cdot \rrbracket$ shares of a. SecureML made an effort in this direction with the use of a garbled circuit technique to compute msb(a) in the 2 PC setting. Later, ABY3 and ASTRA proposed protocols to tackle MSB extraction for the the 3PC setting. ASTRA proposed a constant round protocol but it required a garble circuit version of Parallel Prefix Adder (PPA) to perform the MSB extraction leading to a high communication cost (dependent on the security parameter $\kappa$ ), whereas ABY3 proposed a protocol which used the boolean variant of the PPA circuit trading off the rounds (dependent on the circuit depth) for a more efficient communication cost (independent of the security parameter $\kappa$ ). As our goal is to get a communication efficient protocol we trade-off the rounds and use the boolean variant of PPA circuit proposed by ABY3. The proposed PPA circuit requires $2 \ell$ AND gates leading to a total communication cost of $24 \ell$ bits and has a multiplicative depth of $\log \ell$ rounds. Concretely, given the shares $\llbracket u \rrbracket$ and $\llbracket v \rrbracket$, parties first locally compute $\llbracket \mathrm{a} \rrbracket=\llbracket \mathrm{u} \rrbracket-\llbracket \mathrm{v} \rrbracket$, where $\mathrm{a}=\left(\mu_{\mathrm{a}}^{1}+\mu_{\mathrm{a}}^{2}\right)-\left(\sigma_{\mathrm{a}}^{1}+\sigma_{\mathrm{a}}^{2}\right)$. We observe that, the optimized PPA circuit is a two input circuit which takes two inputs in boolean format and outputs the MSB of the sum of the two inputs. Thus, given $\llbracket \mathrm{a} \rrbracket=\left\{\sigma_{\mathrm{a}}^{1}, \sigma_{\mathrm{a}}^{2}, \mu_{\mathrm{a}}^{1}, \mu_{\mathrm{a}}^{2}\right\}$, we first prepare the following valid inputs: i) $\llbracket \mu_{\mathrm{a}}^{1}+\mu_{\mathrm{a}}^{2} \rrbracket^{\mathbf{B}}$ and ii) $\llbracket-\sigma_{\mathrm{a}}^{1}-\sigma_{\mathrm{a}}^{2} \rrbracket^{\mathbf{B}}$ for the PPA circuit in order to obtain $\llbracket \mathrm{msb}(\mathrm{a}) \rrbracket^{\mathbf{B}}$ as the output. This is achieved by parties executing $\Pi_{\mathrm{cSh}}^{\mathrm{B}}\left(\mathbf{E}, \mu_{\mathrm{a}}^{1}+\mu_{\mathrm{a}}^{2}\right)$ and $\Pi_{\mathrm{cSh}}^{\mathrm{B}}\left(\mathbf{V},-\sigma_{\mathrm{a}}^{1}-\sigma_{\mathrm{a}}^{2}\right)$ protocols respectively. Parties then input their respective shares to the PPA circuit, execute $\Pi_{\text {mult }}$ protocol for each AND gate in the circuit and finally obtain the $\llbracket \cdot \rrbracket^{\mathrm{B}}$ sharing of $\mathrm{msb}(\mathrm{a})$. The ideal functionality $\mathcal{F}_{\text {msb }}$ is presented in Fig 4.10 below.

Functionality $\mathcal{F}_{\text {msb }}$ receives the inputs from the parties as follows:
$-\mathrm{V}_{1}: \llbracket x \rrbracket \mathrm{~V}_{1}$ and internal randomness $\mathrm{I}_{\mathrm{V}_{1}}$.

- $\mathrm{V}_{2}: \llbracket x \rrbracket \mathrm{~V}_{2}$ and internal randomness $\mathrm{I}_{\mathrm{V}_{2}}$.
$-\mathrm{E}_{1}: \llbracket x \rrbracket_{\mathrm{E}_{1}}$ and internal randomness $\mathbf{I}_{\mathrm{E}_{1}}$.
$-\mathrm{E}_{2}: \llbracket x \rrbracket_{\mathrm{E}_{2}}$ and internal randomness $\mathbf{E}_{\mathrm{E}_{2}}$.

On receiving the inputs $\mathcal{F}_{\text {msb }}$ performs the following steps:
$-\mathcal{F}_{\text {msb }}$ sets flag $=1$, if the copies $\sigma_{x}^{1}$ received from $\mathrm{V}_{1}, \mathrm{~V}_{2}$ and $\mathrm{E}_{1}$ mismatch. $\mathcal{F}_{\text {msb }}$ also performs similar checks for $\sigma_{x}^{2}, \mu_{x}^{1}$ and $\mu_{x}^{2}$.

- If flag =1:
- $\mathcal{F}_{\text {msb }}$ uses the internal randomness of the parties, computes all the inputs $i_{1}, \ldots, i_{n}$ of the circuit in clear.
- $\mathcal{F}_{\text {msb }}$ computes $O=f\left(i_{1}, \ldots, i_{n}\right)$ locally, where $O$ denotes the output of the entire circuit
evaluation.
$-\mathcal{F}_{\text {msb }}$ sends the final output $O$ to all the parties.
- Else If flag $=0$ :
- $\mathcal{F}_{\text {msb }}$ computes $x=\mu_{x}^{1}+\mu_{x}^{2}-\sigma_{x}^{1}-\sigma_{x}^{2}$ and set $b=\operatorname{msb}(x)$.
- $\mathcal{F}_{\text {msb }}$ randomly samples $\sigma_{b}^{1}, \sigma_{b}^{2}$ and $\mu_{b}^{1} \in \mathbb{Z}_{2^{1}}$ and set $\mu_{b}^{2}=b \oplus \sigma_{b}^{1} \oplus \sigma_{b}^{2} \oplus \mu_{b}^{1}$.
- The output shares sent by $\mathcal{F}_{\text {bin }}$ are as follows:

$$
\begin{aligned}
& \mathrm{V}_{1}:\left(\sigma_{b}^{1}, \sigma_{b}^{2}, \mu_{b}^{1}\right), \mathrm{V}_{2}:\left(\sigma_{b}^{1}, \sigma_{b}^{2}, \mu_{b}^{2}\right) \\
& \mathrm{E}_{1}:\left(\sigma_{b}^{1}, \mu_{b}^{1}, \mu_{b}^{2}\right), \mathrm{E}_{2}:\left(\sigma_{b}^{2}, \mu_{b}^{1}, \mu_{b}^{2}\right)
\end{aligned}
$$

Figure 4.10: $\mathcal{F}_{\text {msb }}$ : Ideal Functionality for extraction of the MSB bit $b$ from value $x$

Lemma 11. $\Pi_{\text {msb }}$ protocol requires a communication cost (amortized) of $28 \ell$ bits and around $\log \ell+5$ rounds.

Proof. To prepare the input for the optimized Parallel Prefix Adder (PPA) circuit takes 2 calls to $\Pi_{c S h}$ protocol which takes $4 \ell$ bits and at most 2 rounds. The remaining communication and round cost comes from computing the PPA circuit which requires computation of $2 \ell$ AND gates over a depth of $\log \ell+3$ rounds. The communication cost of each AND gate is 12 bits (Lemma 5), thus making the total cost of the circuit as $12 \times 2 \ell=24 \ell$ bits.

### 4.3.1 Security of MSB Extraction

In this section, we describe security proof for our MSB Extraction protocol and prove security in the standard model. Specifically, we prove Theorem 7 in the $\mathcal{F}_{\text {setup }}$ hybrid model.

Theorem 7. Assuming one-way functions, the protocol $\Pi_{\text {msb }}$ securely realizes the functionality $\mathcal{F}_{\text {msb }}$ in the $\mathcal{F}_{\text {setup }}$ hybrid model against one malicious corruption in the standard model.

We give a description of the simulator for the case of a corrupt $\mathrm{V}_{1}$. The case of a corrupt $V_{2}, E_{1}$ and $E_{2}$ is similar to this case and hence can be worked out in a similar way. Note that the PPA circuit primarily consists of AND gates and hence the simulator for $\mathcal{F}_{\text {msb }}$ is required to emulate the simulation steps corresponding to $\mathcal{F}_{\text {cSh }}$ to prepare the inputs for the PPA circuit followed by $\mathcal{F}_{\text {mul }}$ functionality, with respect to each AND gate in the circuit. For the case of corrupt $\bigvee_{1}$, simulator $\mathcal{S}_{\Pi_{\text {msb }}}^{V_{1}}$ first emulates $\mathcal{F}_{\text {cSh }}$ functionality on behalf of $\bigvee_{1}$ to prepare the PPA circuit inputs followed by emulating $\mathcal{F}_{\text {mul }}$ on behalf of $\mathrm{V}_{1}$ for each AND gate in the PPA circuit with the appropriate inputs. Thus at any point if the adversary behaves maliciously the underlying $\mathcal{F}_{\text {cSh }}$ or $\mathcal{F}_{\text {mul }}$ functionality will take care of the misbehavior and give the final circuit output.

### 4.4 Truncation

We use $\ell$-bit integers in signed $2^{\prime}$ s complement form to represent a decimal value where the sign of the decimal value is represented by the most significant bit (MSB). Consider a decimal value z represented in the signed 2's complement form. We use $d_{z}$ to denote the least significant bits that represent its fractional part and $i_{\mathrm{z}}=\ell-d_{\mathrm{z}}$ to represent its integral part. It is observed that in the face of repeated multiplications, $d_{\mathrm{z}}$ and $i_{\mathrm{z}}$ needed to represent the output z keeps doubling with every multiplication and can eventually lead to an overflow. To avoid this multiplication overflow while preserving the accuracy and correctness, truncation is performed at the output of a multiplication gate. Truncation of a value $z$ is defined as $z^{t}=z / 2^{d_{z}}$, where the value $\mathbf{z}$ is right arithmetic shifted by $d_{z}$ bits.

SecureML [MZ17] proposed an efficient truncation method for the two-party setting, where the parties locally truncate the shares after a multiplication. They showed that this technique introduces at most 1 bit error in the least significant bit (LSB) position and thus causes a minor reduction in the accuracy. Later ABY3 [MR18] showed that this idea cannot be trivially extended to three party setting and proposed an alternative technique to achieve truncation. Their main idea revolves around generating $(\llbracket r \rrbracket, \llbracket r \mathrm{t} \rrbracket)$ pair, where $r$ is a random ring element and $r^{t}=r / 2^{d}$. Parties then compute $z-r$ in clear and locally truncate it to obtain $(z-r)^{t}$. This is followed by generating $\llbracket(z-r)^{\mathrm{t}} \rrbracket$ and adding it to $\llbracket r^{\mathrm{t}} \rrbracket$ to obtain $\llbracket z^{\mathrm{t}} \rrbracket$. Similar to SecureML, this technique may also incur a one-bit error in the LSB position of $z^{t}$. To generate $\left(\llbracket r \rrbracket, \llbracket r^{\mathrm{t}} \rrbracket\right)$, ABY3 requires two expensive circuit evaluations and leading to a total cost of more than 100 ring elements per multiplication. While we adopt ABY3's idea of using ( $r, r^{t}$ ) pair in our $\Pi_{\text {mult }}$ protocol to achieve truncation, we remove the need of expensive circuits and maintain the total cost to 14 ring elements.

We begin with the generation of $\left(r, r^{t}\right)$ pair. Parties in $\mathbf{V}$ and $E_{1}$ sample random $r_{1} \in \mathbb{Z}_{2} \ell$, while parties in $V$ and $E_{2}$ sample $r_{2}$. Verifiers $V_{1}$ and $V_{2}$ set $r=r_{1}+r_{2}$. Then parties $V_{1}$ and $V_{2}$ locally truncate $r$ to obtain $r^{\mathrm{t}}$ and execute $\Pi_{c S h}$ to generate $\llbracket r^{\mathrm{t}} \rrbracket$. Thus, the pair $\left([r], \llbracket r^{\mathrm{r}} \rrbracket\right)$ is generated. Unlike $\Pi_{\text {mult }}$ (Figure 3.11), evaluators instead reconstruct ( $z-r$ ), followed by locally truncating it to obtain $(z-r)^{t}$. Evaluators execute $\Pi_{c S h}$ to generate $\llbracket(z-r)^{t} \rrbracket$ followed by locally adding to $\llbracket r^{\mathrm{t}} \rrbracket$ to obtain $\llbracket \mathrm{z}^{\mathrm{t}} \rrbracket$. The formal details of our protocol $\Pi_{\text {multr }}$ and the corresponding functionality $\mathcal{F}_{\text {multr }}$ appears in Fig 4.12 and Fig 4.11 respectively.

Functionality $\mathcal{F}_{\text {multr }}$ receives the inputs from the parties as follows:
$-\mathrm{V}_{1}: \llbracket x \rrbracket \mathrm{~V}_{1}, \llbracket y \rrbracket \mathrm{~V}_{1}$ and internal randomness $\mathrm{I}_{\mathrm{V}_{1}}$.
$-\mathrm{V}_{2}: \llbracket x \rrbracket \mathrm{~V}_{2}, \llbracket y \rrbracket \mathrm{~V}_{2}$ and internal randomness $\mathrm{I}_{\mathrm{V}_{2}}$.

- $\mathrm{E}_{1}: \llbracket x \rrbracket_{\mathrm{E}_{1}}, \llbracket y \rrbracket \rrbracket_{\mathrm{E}_{1}}$ and internal randomness $\mathbf{E}_{\mathbf{E}_{1}}$.
$-\mathrm{E}_{2}: \llbracket x \rrbracket_{\mathrm{E}_{2}}, \llbracket y \rrbracket_{\mathrm{E}_{2}}$ and internal randomness $\mathbf{E}_{\mathrm{E}_{2}}$.

On receiving the inputs $\mathcal{F}_{\text {multr }}$ performs the following steps:
$-\mathcal{F}_{\text {mulTr }}$ computes $\delta_{x y}=\sigma_{x} \sigma_{y}$ using the shares of $\mathrm{V}_{1}$. Similarly, $\mathcal{F}_{\text {mulTr }}$ computes another copy $\delta_{x y}^{\prime}$ using the shares of $\mathrm{V}_{2}$. If $\delta_{x y} \neq \delta_{x y}^{\prime}$, $\mathcal{F}_{\text {multr }}$ sets flag $=1$ else $\mathcal{F}_{\text {mulTr }}$ samples $\delta_{x y}^{1} \in \mathbb{Z}_{2^{\ell}}$ and sets $\delta_{x y}^{2}=\delta_{x y}-\delta_{x y}^{1}$.
$-\mathcal{F}_{\text {mulTr }}$ computes $\mathrm{A}_{1}=-\mu_{\mathrm{x}}^{1} \sigma_{\mathrm{y}}^{1}-\mu_{\mathrm{y}}^{1} \sigma_{\mathrm{x}}^{1}+\delta_{\mathrm{xy}}^{1}+\sigma_{z}^{1}+\Delta_{1}$ using the shares of $\mathrm{V}_{1}$. Similarly, $\mathcal{F}_{\text {mul }}$. computes another copy $A_{1}^{\prime}$ using the shares of $E_{1}$. If $A_{1} \neq A_{1}^{\prime}, \mathcal{F}_{\text {mulTr }}$ sets flag $=1$. Similar steps are performed for the case of $A_{2}, B_{1}$ and $B_{2}$.

- If flag $=1$ :
- $\mathcal{F}_{\text {multr }}$ uses the internal randomness of the parties, computes all the inputs $i_{1}, \ldots, i_{n}$ of the circuit in clear.
- $\mathcal{F}_{\text {multr }}$ computes $O=f\left(i_{1}, \ldots, i_{n}\right)$ locally, where $O$ denotes the output of the entire circuit evaluation.
- $\mathcal{F}_{\text {mulTr }}$ sends the final output $O$ to all the parties.
- Else If flag =0 :
- $\mathcal{F}_{\text {mulTr }}$ computes $x=\mu_{x}^{1}+\mu_{x}^{2}-\sigma_{x}^{1}-\sigma_{x}^{2}, y=\mu_{y}^{1}+\mu_{y}^{2}-\sigma_{y}^{1}-\sigma_{y}^{2}$ and set $z=(x y)^{\mathrm{t}}$, where value $x y$ is truncated by $d$ bits.
- $\mathcal{F}_{\text {mulTr }}$ randomly samples $\sigma_{z}^{1}, \sigma_{z}^{2}$ and $\mu_{z}^{1} \in \mathbb{Z}_{2^{\ell}}$ and set $\mu_{z}^{2}=z+\sigma_{z}^{1}+\sigma_{z}^{2}-\mu_{z}^{1}$.
- The output shares sent by $\mathcal{F}_{\text {multr }}$ are as follows:

$$
\begin{aligned}
& \mathrm{V}_{1}:\left(\sigma_{z}^{1}, \sigma_{z}^{2}, \mu_{z}^{1}\right), \mathrm{V}_{2}:\left(\sigma_{z}^{1}, \sigma_{z}^{2}, \mu_{z}^{2}\right) \\
& \mathrm{E}_{1}:\left(\sigma_{z}^{1}, \mu_{z}^{1}, \mu_{z}^{2}\right), \mathrm{E}_{2}:\left(\sigma_{z}^{2}, \mu_{z}^{1}, \mu_{z}^{2}\right)
\end{aligned}
$$

Figure 4.11: $\mathcal{F}_{\text {mulTr }}$ : Ideal Functionality for truncation of values $x$ and $y$

- Input: Parties input their $\llbracket x \rrbracket$ and $\llbracket y \rrbracket$ shares.
- Output: Parties obtain $\llbracket z^{\mathrm{t}} \rrbracket$ as output, where $z^{\mathrm{t}}=(x y)^{\mathrm{t}}$.
- Parties in $\mathbf{V}$ and $\mathrm{E}_{1}$ collectively sample $\sigma_{z}^{1}$ and $\mathrm{r}_{1}$, while parties in $\mathbf{V}$ and $\mathrm{E}_{2}$ together sample $\sigma_{\mathrm{z}}^{2}$ and $\mathrm{r}_{2}$.
- Verifiers set $r=r_{1}+r_{2}$ and truncate $r$ by $d$ bits to obtain $r^{t}$. Parties execute $\Pi_{c S h}\left(\mathbf{V}, r^{t}\right)$ to generate $\llbracket r^{\mathrm{t}} \rrbracket$ sharing.
- Verifiers locally set $\delta_{x y}=\sigma_{x} \cdot \sigma_{y}$ and compute $\delta_{x y}^{2}=\delta_{x y}-\delta_{x y}^{1}$, where $\delta_{x y}^{1}$ is collectively sampled by parties in $\mathbf{V}$ and $\mathrm{E}_{1}$. Parties then execute $\Pi_{\mathrm{bic}}\left(\mathrm{V}_{1}, \mathrm{~V}_{2}, \delta_{x y}^{2}, \mathrm{E}_{2}, \mathrm{E}_{1}\right)$, such that $\mathrm{E}_{2}$ receives $\delta_{\mathrm{xy}}^{2}$.
- Parties in $\mathbf{V}$ and $\mathrm{E}_{1}$ collectively sample $\Delta_{1}$. Parties $\mathrm{V}_{1}$ and $\mathrm{E}_{1}$ compute
$\mathrm{A}_{1}=-\mu_{\mathrm{x}}^{1} \sigma_{\mathrm{y}}^{1}-\mu_{\mathrm{y}}^{1} \sigma_{\mathrm{x}}^{1}+\delta_{\mathrm{xy}}^{1}-\mathrm{r}_{1}+\Delta_{1}$ and execute $\Pi_{\text {bic }}\left(\mathrm{V}_{1}, \mathrm{E}_{1}, \mathrm{~A}_{1}, \mathrm{E}_{2}, \mathrm{~V}_{2}\right)$, such that $\mathrm{E}_{2}$ receives $\mathrm{A}_{1}$.
- Similarly, parties in $\mathbf{V}$ and $\mathrm{E}_{2}$ collectively sample $\Delta_{2}$. Parties $\mathrm{V}_{1}$ and $\mathrm{E}_{2}$ compute $\mathrm{A}_{2}=-\mu_{\mathrm{x}}^{1} \sigma_{\mathrm{y}}^{2}-\mu_{\mathrm{y}}^{1} \sigma_{\mathrm{x}}^{2}+\delta_{\mathrm{xy}}^{2}-\mathrm{r}_{2}+\Delta_{2}$ and execute $\Pi_{\mathrm{bic}}\left(\mathrm{V}_{1}, \mathrm{E}_{2}, \mathrm{~A}_{2}, \mathrm{E}_{1}, \mathrm{~V}_{2}\right)$, such that $\mathrm{E}_{1}$ receives $\mathrm{A}_{2}$. - Parties $\mathrm{V}_{2}$ and $\mathrm{E}_{1}$ compute $\mathrm{B}_{1}=-\mu_{\mathrm{x}}^{2} \sigma_{\mathrm{y}}^{1}-\mu_{\mathrm{y}}^{2} \sigma_{\mathrm{x}}^{1}-\Delta_{1}$ and execute $\Pi_{\text {bic }}\left(\mathrm{V}_{2}, \mathrm{E}_{1}, \mathrm{~B}_{1}, \mathrm{E}_{2}, \mathrm{~V}_{1}\right)$. Similarly, $\mathrm{V}_{2}$ and $\mathrm{E}_{2}$ compute $\mathrm{B}_{2}=-\mu_{\mathrm{x}}^{2} \sigma_{\mathrm{y}}^{2}-\mu_{\mathrm{y}}^{2} \sigma_{\mathrm{x}}^{2}-\Delta_{2}$ and execute $\Pi_{\text {bic }}\left(\mathrm{V}_{2}, \mathrm{E}_{2}, \mathrm{~B}_{2}, \mathrm{E}_{1}, \mathrm{~V}_{1}\right)$.
- Evaluators compute $z-r=\mu_{x} \mu_{y}+\mathrm{A}_{1}+\mathrm{A}_{2}+\mathrm{B}_{1}+\mathrm{B}_{2}$ and truncate it by $d$ bits to obtain $(z-r)^{t}$.
- Parties execute $\Pi_{c S h}\left(\mathbf{E},(z-r)^{t}\right)$ to generate $\llbracket(z-r)^{t} \rrbracket$ sharing and locally add to obtain $\llbracket \mathrm{z}^{\mathrm{t}} \rrbracket=\llbracket(\mathrm{z}-\mathrm{r})^{\mathrm{t}} \rrbracket+\llbracket \mathrm{r}^{\mathrm{t}} \rrbracket$

Figure 4.12: $\Pi_{\text {multr }}(x, y)$ : Truncation Protocol

Lemma 12. $\Pi_{\text {multr }}$ protocol requires a communication cost (amortized) of $14 \ell$ bits and at most 5 rounds.

Proof. $\Pi_{c S h}$ of $\llbracket r^{\mathrm{t}} \rrbracket$ and $\delta_{x y}$ takes $4 \ell$ bits in total. $\Pi_{\text {bic }}$ of $\mathrm{A}_{1}, \mathrm{~A}_{2}, \mathrm{~B}_{1}$ and $\mathrm{B}_{2}$ takes $8 \ell$ bits followed by $\Pi_{c S h}$ of $(z-r)^{t}$ takes another $2 \ell$ bits. Round complexity wise, in case of a corrupt verifier, $\Pi_{c S h}$ of $\llbracket \mathrm{r}^{\mathrm{t}} \rrbracket$ and $\delta_{x y}$ takes at most 2 rounds. $\Pi_{\text {bic }}$ of $\mathrm{A}_{1}, \mathrm{~A}_{2}, \mathrm{~B}_{1}$ and $\mathrm{B}_{2}$ also takes at most 2 rounds followed by $\Pi_{c S h}$ of $(z-r)^{t}$ consumes 1 round. A similar argument can be made when one of the evaluator is corrupt.

### 4.4.1 Security of Truncation

In this section, we describe the detailed security proof for our Truncation protocol and prove security in the standard model. Specifically, we prove Theorem 8 in the $\mathcal{F}_{\text {setup }}$ hybrid model.

Theorem 8. Assuming one-way functions, the protocol $\Pi_{\text {mulTr }}$ securely realizes the functionality $\mathcal{F}_{\text {multr }}$ in the $\mathcal{F}_{\text {setup }}$ hybrid model against one malicious corruption in the standard model.

We first begin by describing the simulator for the case of a corrupt $\mathrm{V}_{1}$. Note that, $\mathcal{S}_{\Pi_{\text {multr }}}^{\mathrm{V}_{1}}$ already has the knowledge of $\mathrm{I}_{1}, \delta_{x y}^{2}, \mathrm{~A}_{1}, \mathrm{~A}_{2}$ and $\mathrm{r}^{\mathrm{t}}$. Note that only for the case of when $\mathrm{V}_{1}$ acts as a sender in the $\Pi_{\text {bic }}$ protocol, the output of $\Pi_{\text {bic }}$ can lead to pair of honest parties exchanging their internal randomness with each other. Thus $\mathcal{S}_{\Pi_{\text {mulT }}}^{V_{1}}$ emulates the $\mathcal{F}_{\text {bic }}$ functionality on behalf of $\mathrm{V}_{1}$ for each of $\delta_{x y}^{2}, \sigma_{\mathrm{r}^{t}}^{2} \mathrm{~A}_{1}$ and $\mathrm{A}_{2}$. The simulator then checks if any of the output leads to exchange of internal randomness among two pair of honest parties, in which case $\mathcal{S}_{\Pi_{\text {multr }}}^{V_{1}}$ sets $\llbracket \mathrm{x} \rrbracket_{\mathrm{v}_{1}}=(\perp, \perp, \perp), \llbracket \mathrm{y} \rrbracket \mathrm{v}_{1}=(\perp, \perp, \perp)$ shares and invoke the $\mathcal{F}_{\text {mulTr }}$ functionality on behalf of $\mathrm{V}_{1}$.

1) $\mathcal{S}_{\Pi_{\text {mulr }}}^{\vee_{1}}$ emulates $\mathcal{F}_{\text {bic }}$ on behalf of $\bigvee_{1}$ acting as the sender, for $\sigma_{\mathrm{r}}^{2}$. If the internal flag variable
 the case of $\delta_{x y}^{2}, \mathrm{~A}_{1}$ and $\mathrm{A}_{2}$.
2) If flag $=0$ :

- $\mathcal{S}_{\Pi_{\text {mulTr }}}^{\mathrm{V}_{1}}$ emulates $\mathcal{F}_{\text {bic }}$ on behalf of $\mathrm{V}_{1}$ acting as the helper $T$. The simulator also invokes the ideal functionality $\mathcal{F}_{\text {mulTr }}$ on behalf of $\mathrm{V}_{1}$, with inputs as $\llbracket \mathrm{x} \rrbracket \mathrm{V}_{1}$, $\llbracket \mathrm{y} \rrbracket \mathrm{V}_{1}$ and $\mathrm{I}_{\mathrm{V}_{1}}$.

3) Else If flag = 1:

- $\mathcal{S}_{\Pi_{\text {mulTr }}}^{\vee_{1}}$ sets $\llbracket \times \rrbracket \mathrm{V}_{1}=(\perp, \perp, \perp), \llbracket y \rrbracket \mathrm{~V}_{1}=(\perp, \perp, \perp)$ shares and invokes $\mathcal{F}_{\text {multr }}$ on behalf of $\mathrm{V}_{1}$.
$-\delta_{\Pi_{\text {mult }}}^{\vee_{1}}$ sends the final circuit output $O$ to $\bigvee_{1}$ on behalf of the pair of honest parties and discards any incoming message from $V_{1}$.

Figure 4.13: $\mathcal{S}_{\Pi_{\text {multr }}}^{\vee_{1}}$ : Simulator for the case of corrupt $\mathrm{V}_{1}$
This completes the simulation for the case of a corrupt $\mathrm{V}_{1}$. We now describe the simulator for the case of a corrupt $\mathrm{V}_{2}$.

1) $\mathcal{S}_{\Pi_{\text {multr }}}^{\bigvee_{2}}$ emulates $\mathcal{F}_{\text {bic }}$ on behalf of $\bigvee_{2}$ acting as the sender, for $\sigma_{\mathrm{r}^{2}}^{2}$. If the internal flag variable of $\mathcal{F}_{\text {bic }}$ set to 1 , simulator $\mathcal{S}_{\Pi_{\text {mult }}}^{V_{2}}$ sets flag $=1$ and goes to step 3 ). Similar steps are followed for the case of $\delta_{\mathrm{xy}}^{2}, \mathrm{~B}_{1}$ and $\mathrm{B}_{2}$.
2) If flag $=0$ :

- $\mathcal{S}_{\Pi_{\text {multr }}}^{\mathrm{V}_{2}}$ emulates $\mathcal{F}_{\text {bic }}$ on behalf of $\mathrm{V}_{2}$ acting as the receiver $R$. The simulator also invokes the ideal functionality $\mathcal{F}_{\text {mul }}$ on behalf of $\mathrm{V}_{2}$, with inputs as $\llbracket \mathrm{x} \rrbracket \mathrm{V}_{2}, \llbracket \mathrm{y} \rrbracket \mathrm{V}_{2}$ and $\mathrm{I}_{\mathrm{V}_{2}}$.

3) Else If flag = 1:

- $\mathcal{S}_{\Pi_{\text {mulTr }}}^{\vee_{2}}$ sets $\llbracket x \rrbracket \mathrm{~V}_{2}=(\perp, \perp, \perp), \llbracket y \rrbracket \mathrm{~V}_{2}=(\perp, \perp, \perp)$ shares and invokes $\mathcal{F}_{\text {mulTr }}$ on behalf of $\mathrm{V}_{2}$.
$-\mathcal{S}_{\Pi_{\text {mult }}}^{\vee_{2}}$ sends the final circuit output $O$ to $\mathrm{V}_{2}$ on behalf of the pair of honest parties and discards any incoming message from $\mathrm{V}_{2}$.

Figure 4.14: $\mathcal{S}_{\Pi_{\text {multr }}}^{\mathrm{V}_{2}}$ : Simulator for the case of corrupt $\mathrm{V}_{2}$
We describe the simulator for the case of a corrupt a corrupt $E_{1}$. The case of a corrupt $E_{2}$ is similar to this case and hence can be worked out in a similar way.

1) $\mathcal{S}_{\Pi_{\text {mulr }}}^{\mathrm{E}_{1}}$ emulates $\mathcal{F}_{\text {bic }}$ on behalf of $E_{1}$ acting as the sender, for each $A_{1}$ and $B_{1}$.If the internal flag variable of $\mathcal{F}_{\text {bic }}$ set to 1 , simulator $\mathcal{S}_{\Pi_{\text {mult }}}^{\mathrm{E}_{1}}$, sets flag $=1$ and goes to step 3 ).
2) If flag $=0$ :
$-\mathcal{S}_{\Pi_{\text {multr }}}^{\mathrm{E}_{1}}$ emulates $\mathcal{F}_{\text {bic }}$ on behalf of $\mathrm{E}_{1}$, for the case of $\mu_{\mathrm{z}}^{2}$, where $\mathrm{z}=$ xy.If the internal flag variable of $\mathcal{F}_{\text {bic }}$ set to 1 , simulator $\mathcal{S}_{\Pi_{\text {mulTr }}}^{E_{1}}$ sets flag ${ }^{\prime}=1$ and goes to step 3). Else the simulator invokes $\mathcal{F}_{\text {mulTr }}$, with inputs as $\llbracket \times \rrbracket_{\mathrm{E}_{1}}, \llbracket \mathrm{y} \rrbracket_{\mathrm{E}_{1}}$ and $\mathrm{I}_{\mathrm{E}_{1}}$.
3) Else If flag = 1:
$-\mathcal{S}_{\Pi_{\text {multr }}}^{\mathrm{E}_{1}}$ sets $\llbracket \mathrm{x} \rrbracket_{\mathrm{E}_{1}}=(\perp, \perp, \perp), \llbracket \mathrm{y} \rrbracket_{\mathrm{E}_{1}}=(\perp, \perp, \perp)$ shares and invokes $\mathcal{F}_{\text {mulTr }}$ on behalf of $\mathrm{E}_{1}$.
$-\delta_{\Pi_{\text {mulTr }}}^{\mathrm{E}_{1}}$ sends the final circuit output $O$ to $\mathrm{E}_{1}$ on behalf of the pair of honest parties and discards any incoming message from $E_{1}$.

Figure 4.15: $\mathcal{S}_{\Pi_{\text {mult }}}^{\mathrm{E}_{1}}$ : Simulator for the case of corrupt $\mathrm{E}_{1}$

### 4.5 Bit Conversion

Here, we describe a protocol to transform $\llbracket \cdot \rrbracket^{\mathrm{B}}$-sharing of bit $b$ to its arithmetic equivalent. For this transformation, we use the following equivalence relation:

$$
b=\sigma_{b} \oplus \mu_{b}=\mu_{b^{\prime}}+\sigma_{b^{\prime}}-2 \mu_{b^{\prime}} \sigma_{b^{\prime}}
$$

where $\mu_{b^{\prime}}$ and $\sigma_{b^{\prime}}$ denote the bits $\mu_{b}$ and $\sigma_{b}$ respectively over $\mathbb{Z}_{2^{2}}$. Parties who hold $\mu_{b}$ and $\sigma_{b}$ in clear convert them to $\mu_{b^{\prime}}$ and $\sigma_{b^{\prime}}$ respectively. Parties generate $\llbracket \cdot \rrbracket$-sharing of $\sigma_{b^{\prime}}$ and $\mu_{b^{\prime}}$ by executing $\Pi_{c S h}$ followed by multiplication of $\llbracket \mu_{b^{\prime}} \rrbracket$ and $\llbracket \sigma_{b^{\prime}} \rrbracket$. The formal details of the resultant protocol $\Pi_{\mathrm{btr}}$ and the corresponding functionality $\mathcal{F}_{\mathrm{btr}}$ are given in 4.17 and Fig 4.16 respectively.

Functionality $\mathcal{F}_{\text {bin }}$ receives the inputs from the parties as follows:
$-\mathrm{V}_{1}: \llbracket b \rrbracket_{\mathrm{V}_{1}}^{\mathrm{B}}$ and internal randomness $\mathrm{I}_{\mathrm{V}_{1}}$.
$-\mathrm{V}_{2}: \llbracket b \rrbracket_{\mathrm{V}_{2}}^{\mathrm{B}}$ and internal randomness $\mathrm{I}_{\mathrm{V}_{2}}$.
$-\mathrm{E}_{1}: \llbracket b \rrbracket_{\mathrm{E}_{1}}^{\mathrm{B}}$ and internal randomness $\mathrm{I}_{\mathrm{E}_{1}}$.
$-\mathrm{E}_{2}: \llbracket b \rrbracket_{\mathrm{E}_{2}}^{\mathrm{B}}$ and internal randomness $\mathrm{I}_{\mathrm{E}_{2}}$.

On receiving the inputs $\mathcal{F}_{\text {btr }}$ performs the following steps:

- $\mathcal{F}_{\text {btr }}$ sets flag $=1$, if the copies $\sigma_{b}^{1}$ received from $\mathrm{V}_{1}, \mathrm{~V}_{2}$ and $\mathrm{E}_{1}$ mismatch. $\mathcal{F}_{\text {btr }}$ also performs similar checks for $\sigma_{b}^{2}, \mu_{b}^{1}$ and $\mu_{b}^{2}$.
- If flag = 1 :
- $\mathcal{F}_{\text {btr }}$ uses the internal randomness of the parties, computes all the inputs $i_{1}, \ldots, i_{n}$ of the circuit in clear.
- $\mathcal{F}_{\text {btr }}$ computes $O=f\left(i_{1}, \ldots, i_{n}\right)$ locally, where $O$ denotes the output of the entire circuit evalu-
ation.
- $\mathcal{F}_{\text {btr }}$ sends the final output $O$ to all the parties.
- Else If flag = 0 :
- $\mathcal{F}_{\text {btr }}$ computes $b=\mu_{b}^{1} \oplus \mu_{b}^{2} \oplus \sigma_{b}^{1} \oplus \sigma_{b}^{2}$ and set $z=b$.
- $\mathcal{F}_{\text {bin }}$ randomly samples $\sigma_{z}^{1}, \sigma_{z}^{2}$ and $\mu_{z}^{1} \in \mathbb{Z}_{2^{\ell}}$ and set $\mu_{z}^{2}=z+\sigma_{z}^{1}+\sigma_{z}^{2}-\mu_{z}^{1}$.
- The output shares sent by $\mathcal{F}_{\text {bin }}$ are as follows:

$$
\begin{aligned}
& \mathrm{V}_{1}:\left(\sigma_{z}^{1}, \sigma_{z}^{2}, \mu_{z}^{1}\right), \mathrm{V}_{2}:\left(\sigma_{z}^{1}, \sigma_{z}^{2}, \mu_{z}^{2}\right) \\
& \mathrm{E}_{1}:\left(\sigma_{z}^{1}, \mu_{z}^{1}, \mu_{z}^{2}\right), \mathrm{E}_{2}:\left(\sigma_{z}^{2}, \mu_{z}^{1}, \mu_{z}^{2}\right)
\end{aligned}
$$

Figure 4.16: $\mathcal{F}_{\text {btr }}$ : Ideal Functionality for conversion of bit $b$

- Input: Parties input their $\llbracket b \rrbracket^{\mathbf{B}}$ shares.
- Output: Parties obtain $\llbracket b \rrbracket$ as the output.
- Parties execute $\Pi_{\mathrm{cSh}}\left(\mathbf{V}, \sigma_{b^{\prime}}\right)$ and $\Pi_{\mathrm{CSh}}\left(\mathbf{E}, \mu_{b^{\prime}}\right)$ to generate $\llbracket \sigma_{b^{\prime}} \rrbracket$ and $\llbracket \mu_{b^{\prime}} \rrbracket$ respectively.
- Parties execute $\Pi_{\text {mult }} \mu_{b^{\prime}} \sigma_{b^{\prime}}$ to generate $\llbracket \mu_{b^{\prime}} \sigma_{b^{\prime}} \rrbracket$, followed by locally computing $\llbracket b \rrbracket=\llbracket \mu_{b^{\prime}} \rrbracket+\llbracket \sigma_{b^{\prime}} \rrbracket-2 \llbracket \mu_{b^{\prime}} \sigma_{b^{\prime}} \rrbracket$.

Figure 4.17: $\Pi_{b t r}\left(\llbracket b \rrbracket^{\mathbf{B}}\right)$ : Conversion of a bit to arithmetic equivalent
We observe that cost of multiplication in $\Pi_{\mathrm{btr}}$ can be reduced from $12 \ell$ to $10 \ell$ bits. Note that the value $\sigma_{\mu_{b^{\prime}}}$ is set to zero, when $\Pi_{c S h}$ is executed to generate $\llbracket \mu_{b^{\prime}} \rrbracket$. This implies $\delta_{\mu_{b^{\prime}}} \sigma_{b^{\prime}}=0$ and thus removes the extra call to $\Pi_{\text {bic }}$ protocol.

Lemma 13. $\Pi_{b t r}$ protocol requires a communication cost (amortized) of $14 \ell$ bits and at most 5 rounds.

Proof. Firstly, the protocol $\Pi_{\mathrm{cSh}}$ used to generate the arithmetic equivalent $\llbracket \cdot \rrbracket$-sharing of bit $\sigma_{b}$ and $\mu_{b}$ consumes $4 \ell$ bits in total. The optimized multiplication of $\mu_{b^{\prime}}, \sigma_{b^{\prime}}$ consumes $10 \ell$ bits in total as $\delta_{\mu_{b^{\prime}} \sigma_{b^{\prime}}}=0$ so $\Pi_{\mathrm{cSh}}$ is not required the same. In case of a corrupt verifier $\Pi_{\mathrm{cSh}}$ of $\sigma_{b}$ can take at most 2 rounds, followed by 3 rounds for optimized multiplication (as $\delta_{\mu_{b^{\prime}} \sigma_{b^{\prime}}}=0$ ) making the total rounds equal to 5 . A similar argument can be made for the case when one of the evaluator is corrupt.

### 4.5.1 Security of Bit Conversion

In this section, we describe the ideal functionality followed by a detailed security proof for our Bit Conversion protocol and prove security in the standard model. Specifically, we prove Theorem 9 in the $\mathcal{F}_{\text {setup }}$ hybrid model.

Theorem 9. Assuming one-way functions, the protocol $\Pi_{\mathrm{btr}}$ securely realizes the functionality $\mathcal{F}_{\text {btr }}$ in the $\mathcal{F}_{\text {setup }}$ hybrid model against one malicious corruption in the standard model.

We first begin by describing the simulator for the case of a corrupt $\mathrm{V}_{1}$. The case of a corrupt $\mathrm{V}_{2}$ is similar to this case and hence can be worked out in a similar way.

1) $\mathcal{S}_{\Pi_{\text {btr }}}^{\vee_{1}}$ emulates $\mathcal{F}_{\text {bic }}$ on behalf of $\bigvee_{1}$ acting as the helper for $\mu_{\mu_{b^{\prime}}}^{2}$ and acting as the sender for $\sigma_{\sigma_{b^{\prime}}}^{2}$, If the internal flag variable of $\mathcal{F}_{\text {bic }}$ set to 1 , simulator $\mathcal{S}_{\Pi_{b \text { br }}}^{V_{1}}$, sets flag $=1$ and goes to step 4).
2) Simulator $\mathcal{S}_{\Pi_{\text {mbs }}}^{\vee_{1}}$ then simulates the steps of $\mathcal{S}_{\Pi_{\text {mutt }}}^{\vee_{1}}$ (Figure 3.12) on behalf of $\bigvee_{1}$ for the product $\mu_{b^{\prime}} \sigma_{b^{\prime}}$.
3) If flag $=0$ :

- The simulator also invokes the ideal functionality $\mathcal{F}_{\text {btr }}$ on behalf of $\mathrm{V}_{1}$, with inputs as $\llbracket \mathrm{b} \rrbracket_{\mathrm{V}_{1}}^{\mathrm{B}}$ and $\mathrm{I}_{1}$.

4) Else If flag = 1:
$-\mathcal{S}_{\Pi_{\mathrm{btr}}}^{\mathrm{V}_{1}}$ sets $\llbracket \mathrm{b} \rrbracket \mathbb{V}_{1}^{\mathrm{B}}=(\perp, \perp, \perp)$ and invokes $\mathcal{F}_{\text {btr }}$ on behalf of $\mathrm{V}_{1}$.
$-\mathcal{S}_{\Pi_{\mathrm{btr}}}^{\vee_{1}}$ sends the final circuit output $O$ to $\mathrm{V}_{1}$ on behalf of the pair of honest parties and discards any incoming message from $\mathrm{V}_{1}$.

Figure 4.18: $\mathcal{S}_{\Pi_{\text {btr }}}^{V_{1}}$ : Simulator for the case of corrupt $\mathrm{V}_{1}$
We now describe the simulator for the case of a corrupt a corrupt $\mathrm{E}_{1}$. The case of a corrupt $\mathrm{E}_{2}$ is similar to this case and hence can be worked out in a similar way.

1) $\mathcal{S}_{\Pi_{\mathrm{btr}}}^{\mathrm{E}_{1}}$ emulates $\mathcal{F}_{\text {bic }}$ on behalf of $\mathrm{E}_{1}$ acting as the helper for $\sigma_{\sigma_{\mathrm{b}^{\prime}}}^{2}$ and acting as the sender for $\mu_{\mu_{\mathrm{b}^{\prime}}}^{2}$. If the internal flag variable of $\mathcal{F}_{\text {bic }}$ set to 1 , simulator $\mathcal{S}_{\Pi_{\mathrm{btr}}}^{\mathrm{E}_{1}}$ sets flag $=1$ and goes to step 4).
2) $\mathcal{S}_{\Pi_{\text {msb }}}^{\mathrm{E}_{1}}$ then simulates the steps of $\mathcal{S}_{\Pi_{\text {mult }}}^{\mathrm{E}_{1}}$ (Figure 3.14) on behalf of $\mathrm{E}_{1}$ for the product $\mu_{b^{\prime}} \sigma_{b^{\prime}}$.
3) If flag $=0$ :

- The simulator also invokes $\mathcal{F}_{\text {btr }}$ on behalf of $E_{1}$, with inputs as $\llbracket b \rrbracket_{E_{1}}^{B}$ and $I_{E_{1}}$.

4) Else If flag = 1 :
$-\mathcal{S}_{\Pi_{\text {btr }}}^{\mathrm{E}_{1}}$ sets $\llbracket b \rrbracket_{\mathrm{E}_{1}}^{\mathrm{B}}=(\perp, \perp, \perp)$ and invokes $\mathcal{F}_{\text {btr }}$ on behalf of $\mathrm{E}_{1}$.
$-S_{\Pi_{\text {btr }}}^{\mathrm{E}_{1}}$ sends the final circuit output $O$ to $\mathrm{E}_{1}$ on behalf of the pair of honest parties and discards any incoming message from $E_{1}$.

Figure 4.19: $\mathcal{S}_{\Pi_{b \text { brt }}}^{\mathrm{E}_{1}}$ : Simulator for the case of corrupt $\mathrm{E}_{1}$

### 4.6 Bit Insertion

Given a bit $b \in\{0,1\}$ in $\llbracket \cdot \rrbracket^{\mathbf{B}}$-shared form and $x \in \mathbb{Z}_{2^{\ell}}$ in $\llbracket \cdot \rrbracket$-shared form, we have to compute $\llbracket b x \rrbracket$. A trivial solution is to convert $\llbracket b \rrbracket^{\mathrm{B}}$ to $\llbracket b \rrbracket$ using $\Pi_{\mathrm{btr}}$ followed by a multiplication with $\llbracket x \rrbracket$, which requires a total of 26 ring elements and 10 rounds. Instead, we propose a better solution that requires $18 \ell$ ring elements and 5 rounds in total. We can view the equation for bit insertion as follows:

$$
\begin{aligned}
\mu_{b x} & =\left(\mu_{b} \oplus \sigma_{b}\right) \cdot\left(\mu_{x}-\sigma_{x}\right)+\sigma_{b x} \\
& =\left(\mu_{b^{\prime}}+\sigma_{b^{\prime}}-2 \mu_{b^{\prime}} \sigma_{b^{\prime}}\right) \cdot\left(\mu_{x}-\sigma_{x}\right)+\sigma_{b x} \\
& =\gamma_{b^{\prime} x}-\mu_{b^{\prime}} \sigma_{x}+\left(\mu_{x}-2 \gamma_{b^{\prime} x}\right) \sigma_{b^{\prime}}+\left(2 \mu_{b^{\prime}}-1\right) \delta_{b^{\prime} x}+\sigma_{b x} \\
& =\gamma_{b^{\prime} x}+\left(-\mu_{b^{\prime}}^{1} \sigma_{x}+\left(\mu_{x}^{1}-2 \gamma_{b^{\prime} x}^{1}\right) \sigma_{b^{\prime}}+\left(2 \mu_{b^{\prime}}^{1}-1\right) \delta_{b^{\prime} x}+\sigma_{b x}\right) \\
& +\left(-\mu_{b^{\prime}}^{2} \sigma_{x}+\left(\mu_{x}^{2}-2 \gamma_{b^{\prime} x}^{2}\right) \sigma_{b^{\prime}}+\left(2 \mu_{b^{\prime}}^{2}-1\right) \delta_{b^{\prime} x}\right) \\
& =\gamma_{b^{\prime} x}+\left(\mathrm{A}_{1}+\mathrm{A}_{2}\right)+\left(\mathrm{B}_{1}+\mathrm{B}_{2}\right)
\end{aligned}
$$

where $\gamma_{b^{\prime} x}=\mu_{b^{\prime}} \mu_{x}, \delta_{b^{\prime} x}=\sigma_{b^{\prime}} \sigma_{x}$ and $\mu_{b^{\prime}}, \sigma_{b^{\prime}}$ represent $\mu_{b}$ and $\sigma_{b}$ over $\mathbb{Z}_{2^{\ell}}$ respectively. In the above equation, we observe that, given the [•]-shares of $\mu_{b^{\prime}}, \sigma_{b^{\prime}}, \quad \gamma_{b^{\prime} x}$ and $\delta_{b^{\prime} x}$, parties can robustly compute $\llbracket \cdot \rrbracket$-sharing of $\mu_{b x}$. The protocol proceeds as follows: Parties begin by generating $[\cdot]$-shares of $\mu_{b^{\prime}}, \gamma_{b^{\prime} x}$ towards set $\mathbf{V}$ and $\sigma_{b^{\prime}}, \delta_{b^{\prime} x}$ towards set $\mathbf{E}$, so that parties can compute $A_{1}, A_{2}, B_{1}$ and $B_{2}$. This is followed by parties executing $\Pi_{\text {bic }}$ protocol for each $A_{i}$ and $\mathrm{B}_{i}$, so that $\mathrm{E}_{1}$ and $\mathrm{E}_{2}$ are able to compute $\mu_{b x}$. The formal details of the protocol $\Pi_{\mathrm{bin}}$ and the corresponding functionality $\mathcal{F}_{\text {bin }}$ appear in Fig 4.21 and Fig 4.20 respectively.

Functionality $\mathcal{F}_{\text {bin }}$ receives the inputs from the parties as follows:
$-\mathrm{V}_{1}: \llbracket x \rrbracket \mathrm{~V}_{1}, \llbracket b \rrbracket \mathrm{~V}_{1} \mathrm{~B}$ and internal randomness $\mathrm{I}_{\mathrm{V}_{1}}$.
$-\mathrm{V}_{2}: \llbracket x \rrbracket_{\mathrm{V}_{2}}, \llbracket b \rrbracket_{\mathrm{V}_{2}}^{\mathrm{B}}$ and internal randomness $\mathrm{I}_{\mathrm{V}_{2}}$.
$-\mathrm{E}_{1}: \llbracket x \rrbracket_{\mathrm{E}_{1}}, \llbracket b \rrbracket_{\mathrm{E}_{1}}^{\mathrm{B}}$ and internal randomness $\mathbf{I}_{\mathrm{E}_{1}}$.
$-\mathrm{E}_{2}: \llbracket x \rrbracket_{\mathrm{E}_{2}}, \llbracket b \rrbracket_{\mathrm{E}_{2}}^{\mathrm{B}}$ and internal randomness $\mathrm{I}_{\mathrm{E}_{2}}$.

On receiving the inputs $\mathcal{F}_{\text {bin }}$ performs the following steps:

- $\mathcal{F}_{\text {bin }}$ sets flag $=1$, if the copies $\sigma_{b}^{1}$ received from $\mathrm{V}_{1}, \mathrm{~V}_{2}$ and $\mathrm{E}_{1}$ mismatch. $\mathcal{F}_{\text {bin }}$ also performs similar checks for $\sigma_{b}^{2}, \mu_{b}^{1}$ and $\mu_{b}^{2}$.
- A similar check is performed by $\mathcal{F}_{\text {bin }}$ for the shares of $\llbracket x \rrbracket$.
- If flag = 1 :
- $\mathcal{F}_{\text {bin }}$ uses the internal randomness of the parties, computes all the inputs $i_{1}, \ldots, i_{n}$ of the circuit
in clear.
- $\mathcal{F}_{\text {bin }}$ computes $O=f\left(i_{1}, \ldots, i_{n}\right)$ locally, where $O$ denotes the output of the entire circuit evaluation.
- $\mathcal{F}_{\text {bin }}$ sends the final output $O$ to all the parties.
- Else If flag = 0 :
- $\mathcal{F}_{\text {bin }}$ computes $x=\mu_{x}^{1}+\mu_{x}^{2}-\sigma_{x}^{1}-\sigma_{x}^{2}, b=\mu_{b}^{1} \oplus \mu_{b}^{2} \oplus \sigma_{b}^{1} \oplus \sigma_{b}^{2}$ and set $z=b x$, where $z=x$ if $b=1$ else $z=0$.
- $\mathcal{F}_{\text {bin }}$ randomly samples $\sigma_{z}^{1}, \sigma_{z}^{2}$ and $\mu_{z}^{1} \in \mathbb{Z}_{2^{\ell}}$ and set $\mu_{z}^{2}=z+\sigma_{z}^{1}+\sigma_{z}^{2}-\mu_{z}^{1}$.
- The output shares sent by $\mathcal{F}_{\text {bin }}$ are as follows:

$$
\begin{aligned}
& \mathrm{V}_{1}:\left(\sigma_{z}^{1}, \sigma_{z}^{2}, \mu_{z}^{1}\right), \mathrm{V}_{2}:\left(\sigma_{z}^{1}, \sigma_{z}^{2}, \mu_{z}^{2}\right) \\
& \mathrm{E}_{1}:\left(\sigma_{z}^{1}, \mu_{z}^{1}, \mu_{z}^{2}\right), \mathrm{E}_{2}:\left(\sigma_{z}^{2}, \mu_{z}^{1}, \mu_{z}^{2}\right)
\end{aligned}
$$

Figure 4.20: $\mathcal{F}_{\text {bin }}$ : Ideal Functionality for bit insertion of bit $b$ into value $x$

- Input: Parties input their $\llbracket b \rrbracket^{\mathbf{B}}$ and $\llbracket x \rrbracket$ shares.
- Output: Parties obtain $\llbracket b x \rrbracket$ as the output.
- Parties in $\mathbf{V}$ and $\mathbf{E}_{1}$ collectively sample random $\sigma_{b x}^{1} \in \mathbb{Z}_{2}$, while parties in $\mathbf{V}$ and $\mathbf{E}_{2}$ together sample random $\sigma_{b x}^{2}$.
- Parties in $\mathbf{V}$ and $\mathbf{E}_{1}$ collectively sample random $\sigma_{b^{\prime}}^{1}$ followed by $\mathrm{V}_{1}$ and $\mathrm{V}_{2}$ setting $\sigma_{b^{\prime}}^{2}=\sigma_{b^{\prime}}-\sigma_{b^{\prime}}^{1}$. Parties then execute $\Pi_{\text {bic }}\left(\mathrm{V}_{1}, \mathrm{~V}_{2}, \sigma_{b^{\prime}}^{2}, \mathrm{E}_{2}, \mathrm{E}_{1}\right)$, such that $\mathrm{E}_{2}$ receives $\sigma_{b^{\prime}}^{2}$. The same procedure is used for $\mathrm{E}_{2}$ to receive $\delta_{b^{\prime} x}^{2}$.
- Parties in $\mathbf{E}$ and $V_{1}$ collectively sample random $\mu_{b^{\prime}}^{1}$ followed by $\mathbf{E}_{1}$ and $\mathbf{E}_{2}$ setting $\mu_{b^{\prime}}^{2}=\mu_{b^{\prime}}-\mu_{b^{\prime}}^{1}$. Parties then execute $\Pi_{\text {bic }}\left(\mathrm{E}_{1}, \mathrm{E}_{2}, \mu_{b^{\prime}}^{2}, \mathrm{~V}_{2}, \mathrm{~V}_{1}\right)$, such that $\mathrm{V}_{2}$ receives $\mu_{b^{\prime}}^{2}$. The same procedure is used for $\mathrm{V}_{2}$ to receive $\gamma_{b^{\prime} x}^{2}$.
- Parties in $\mathbf{V}$ and $\mathbf{E}_{1}$ collectively sample $\Delta_{1}$. Parties $\mathrm{V}_{1}$ and $\mathrm{E}_{1}$ compute $\mathrm{A}_{1}=-\mu_{b^{\prime}}^{1} \sigma_{x}^{1}+\left(\mu_{x}^{1}-\right.$ $\left.2 \gamma_{b^{\prime} x}^{1}\right) \sigma_{b^{\prime}}^{1}+\left(2 \mu_{b^{\prime}}^{1}-1\right) \delta_{b^{\prime} x}^{1}+\sigma_{b x}^{1}+\Delta_{1}$ and invoke $\Pi_{\text {bic }}\left(\mathrm{V}_{1}, \mathrm{E}_{1}, \mathrm{~A}_{1}, \mathrm{E}_{2}, \mathrm{~V}_{2}\right)$.
- Similarly, parties in $\mathbf{V}$ and $\mathrm{E}_{2}$ collectively sample $\Delta_{2}$. Parties $\mathrm{V}_{1}$ and $\mathrm{E}_{2}$ compute $\mathrm{A}_{2}=-\mu_{b^{\prime}}^{1} \sigma_{x}^{2}+$ $\left(\mu_{x}^{1}-2 \gamma_{b^{\prime} x}^{1}\right) \sigma_{b^{\prime}}^{2}+\left(2 \mu_{b^{\prime}}^{1}-1\right) \delta_{b^{\prime} x}^{2}+\sigma_{b x}^{2}+\Delta_{2}$ and invoke $\Pi_{\text {bic }}\left(\mathrm{V}_{1}, \mathrm{E}_{2}, \mathrm{~A}_{2}, \mathrm{E}_{1}, \mathrm{~V}_{2}\right)$.
- Parties $\mathrm{V}_{2}$ and $\mathrm{E}_{1}$ compute $\mathrm{B}_{1}=-\mu_{b^{\prime}}^{2} \sigma_{x}^{1}+\left(\mu_{x}^{2}-2 \gamma_{b^{\prime} x}^{2}\right) \sigma_{b^{\prime}}^{1}+\left(2 \mu_{b^{\prime}}^{2}-1\right) \delta_{b^{\prime} x}^{1}-\Delta_{1}$ and invoke $\Pi_{\text {bic }}\left(\mathrm{V}_{2}, \mathrm{E}_{1}, \mathrm{~B}_{1}, \mathrm{E}_{2}, \mathrm{~V}_{1}\right)$. Similarly, $\mathrm{V}_{2}$ and $\mathrm{E}_{2}$ compute $\mathrm{B}_{2}=-\mu_{b^{\prime}}^{2} \sigma_{x}^{2}+\left(\mu_{x}^{2}-2 \gamma_{b^{\prime} x}^{2}\right) \sigma_{b^{\prime}}^{2}+\left(2 \mu_{b^{\prime}}^{2}-\right.$ 1) $\delta_{b^{\prime} x}^{2}-\Delta_{2}$ and invoke $\Pi_{\text {bic }}\left(\mathrm{V}_{2}, \mathrm{E}_{2}, \mathrm{~B}_{2}, \mathrm{E}_{1}, \mathrm{~V}_{1}\right)$.
- Evaluators compute $\mu_{b^{\prime} x}=\mathrm{A}_{1}+\mathrm{A}_{2}+\mathrm{B}_{1}+\mathrm{B}_{2}+\gamma_{b^{\prime} x}$ locally. Parties in $\mathbf{E}$ and $\mathrm{V}_{1}$ collectively sample $\mu_{b^{\prime} x}^{1}$ followed by evaluators setting $\mu_{b^{\prime} x}^{2}=\mu_{b^{\prime} x}-\mu_{b^{\prime} x}^{1}$ and invoking $\Pi_{\text {bic }}\left(\mathrm{E}_{1}, \mathrm{E}_{2}, \mu_{b^{\prime} x}^{2}, \mathrm{~V}_{2}, \mathrm{~V}_{1}\right)$.

Figure 4.21: $\Pi_{\mathrm{bin}}\left(\llbracket \mathrm{b} \rrbracket^{\mathrm{B}}, \llbracket x \rrbracket\right)$ : Insertion of bit b in a value

Lemma 14. $\Pi_{b i n}$ protocol requires a communication cost (amortized) of $18 \ell$ bits and at most 5 rounds.

Proof. Four calls to $\Pi_{\text {bic }}$ for $\sigma_{b^{\prime}}^{2}, \mu_{b^{\prime}}^{2}, \gamma_{b^{\prime} x}$ and $\delta_{b^{\prime} x}$ consumes $8 \ell$ bits in total. Again four calls to $\Pi_{\text {bic }}$ each for $A_{1}, A_{2}, B_{1}$ and $B_{2}$ consumes another $8 \ell$ bits followed by evaluators invoking $\Pi_{\text {bic }}$ of $\mu_{b^{\prime} x}^{2}$ which consumes $2 \ell$ bits. Round complexity wise, in case of a corrupt verifier, $\Pi_{\text {bic }}$ for $\sigma_{b^{\prime}}^{2}, \mu_{b^{\prime}}^{2}, \gamma_{b^{\prime} x}$ and $\delta_{b^{\prime} x}$ takes at most 2 rounds, followed by $\Pi_{\text {bic }}$ of $\mathrm{A}_{1}, \mathrm{~A}_{2}, \mathrm{~B}_{1}$ and $\mathrm{B}_{2}$ which consumes at most 2 more rounds. Finally, $\Pi_{\text {bic }}$ of $\mu_{b^{\prime} x}^{2}$ which requires 1 round. A similar argument can be made when one of the evaluator is corrupt.

### 4.6.1 Security of Bit Conversion

In this section, we describe the ideal functionality followed by a detailed security proof for our Bit Insertion protocol and prove security in the standard model. Specifically, we prove Theorem 10 in the $\mathcal{F}_{\text {setup }}$ hybrid model.

Theorem 10. Assuming one-way functions, the protocol $\Pi_{\mathrm{bin}}$ securely realizes the functionality $\mathcal{F}_{\text {bin }}$ in the $\mathcal{F}_{\text {setup }}$ hybrid model against one malicious corruption in the standard model.

We first describe the simulator for the case of a corrupt $\mathrm{V}_{1}$. Note that, $\mathcal{S}_{\Pi_{1} \text { bin }}^{V_{1}}$ already has the knowledge of $\mathrm{I}_{1}, \sigma_{b^{\prime}}^{2}, \delta_{\mathrm{xy}}^{2}, \mathrm{~A}_{1}$ and $\mathrm{A}_{2}$. $\mathcal{S}_{\Pi_{\text {bin }}}^{\vee_{1}}$ emulates the $\mathcal{F}_{\text {bic }}$ functionality on behalf of $\mathrm{V}_{1}$ for each of $\sigma_{b^{\prime}}^{2}, \delta_{x y}^{2}, \mathrm{~A}_{1}$ and $\mathrm{A}_{2}$. The simulator then checks if any of the output leads to exchange of internal randomness among two pair of honest parties, in which case $\mathcal{S}_{\Pi_{\text {bin }}}^{V_{1}}$ prepares incorrect $\llbracket \mathrm{x} \rrbracket \mathrm{V}_{1}$ and $\llbracket b \rrbracket_{\mathrm{V}_{1}}^{\mathrm{B}}$ shares and invoke the $\mathcal{F}_{\text {bin }}$ functionality on behalf of $\mathrm{V}_{1}$.

1) $\mathcal{S}_{\Pi_{\text {bin }}}^{\vee_{1}}$ emulates $\mathcal{F}_{\text {bic }}$ on behalf of $\bigvee_{1}$ acting as the sender, for $\sigma_{b^{\prime}}^{2}$. If the internal flag variable of $\mathcal{F}_{\text {bic }}$ is set to 1 , simulator $\mathcal{S}_{\Pi_{\text {bin }}}^{V_{1}}$ sets flag $=1$ and goes to step 4). Similar steps are followed for the case of $\delta_{\mathrm{xy}}^{2}, \mathrm{~A}_{1}$ and $\mathrm{A}_{2}$.
2) $\mathcal{S}_{\Pi_{\text {bin }}}^{V_{1}}$ also emulates $\mathcal{F}_{\text {bic }}$ on behalf of $V_{1}$ acting as the helper, for $\mu_{b^{\prime}}^{2}$.
3) If flag $=0$ :

- $\mathcal{S}_{\Pi_{\text {bin }}}^{\vee_{1}}$ emulates $\mathcal{F}_{\text {bic }}$ on behalf of $\bigvee_{1}$ acting as the helper $T$. The simulator also invokes the ideal functionality $\mathcal{F}_{\text {bin }}$ on behalf of $\mathrm{V}_{1}$, with inputs as $\llbracket \times \rrbracket \mathbb{V}_{1}, \llbracket b \rrbracket_{\mathrm{V}_{1}}^{\mathrm{B}}$ and $\boldsymbol{I}_{\mathrm{V}_{1}}$.

4) Else If flag = 1:

- $\mathcal{S}_{\Pi_{\text {bin }}}^{\mathrm{V}_{1}}$ sets $\llbracket \times \rrbracket_{\mathrm{V}_{1}}=(\perp, \perp, \perp), \llbracket b \rrbracket_{\mathrm{V}_{1}}^{\mathrm{B}}=(\perp, \perp, \perp)$ and invokes $\mathcal{F}_{\text {bin }}$ on behalf of $\mathrm{V}_{1}$.
$-\mathcal{S}_{\Pi_{\text {bin }}}^{\vee_{1}}$ sends the final circuit output $O$ to $\bigvee_{1}$ on behalf of the pair of honest parties and discards any incoming message from $V_{1}$.

Figure 4.22: $\mathcal{S}_{\Pi_{\text {bin }}}^{V_{1}}$ : Simulator for the case of corrupt $V_{1}$
This completes the simulation for the case of a corrupt $\mathrm{V}_{1}$. We now describe the simulator for the case of a corrupt $\mathrm{V}_{2}$.

1) $\mathcal{S}_{\Pi_{\text {bin }}}^{\bigvee_{2}}$ emulates $\mathcal{F}_{\text {bic }}$ on behalf of $\bigvee_{2}$ acting as the sender, for $\sigma_{b^{\prime}}^{2}$. If the internal flag variable of $\mathcal{F}_{\text {bic }}$ is set to 1 , simulator $\mathcal{S}_{\Pi_{\text {bin }}}^{V_{2}}$ sets flag $=1$ and goes to step 4). Similar steps are followed for the case of $\delta_{\mathrm{xy}}^{2}, \mathrm{~B}_{1}$ and $\mathrm{B}_{2}$.
2) $\mathcal{S}_{\Pi_{\text {bin }}}^{\vee_{2}}$ additionally emulates $\mathcal{F}_{\text {bic }}$ on behalf of $\bigvee_{2}$ acting as the receiver, for $\mu_{b^{\prime}}^{2}$.
3) If flag $=0$ :

- $\mathcal{S}_{\Pi_{\text {bin }}}^{\bigvee_{2}}$ emulates $\mathcal{F}_{\text {bic }}$ on behalf of $\mathrm{V}_{2}$ acting as the receiver $R$. The simulator also invokes the ideal functionality $\mathcal{F}_{\text {bin }}$ on behalf of $V_{2}$, with inputs as $\left.\llbracket x \rrbracket \rrbracket_{V_{2}}, \llbracket b\right]_{\mathrm{V}_{2}}^{\mathrm{B}}$ and $\mathrm{I}_{\mathrm{V}_{2}}$.

4) Else If flag = 1:
$-\mathcal{S}_{\Pi_{\text {bin }}}^{\mathrm{V}_{2}}$ sets $\llbracket \mathrm{x} \rrbracket \mathbb{V}_{2}=(\perp, \perp, \perp), \llbracket b \rrbracket_{\mathrm{V}_{2}}^{\mathrm{B}}=(\perp, \perp, \perp)$ and invokes $\mathcal{F}_{\text {bin }}$ on behalf of $\mathrm{V}_{2}$.
$-\mathcal{S}_{\Pi_{\text {bin }}}^{\vee_{2}}$ sends the final circuit output $O$ to $\bigvee_{2}$ on behalf of the pair of honest parties and discards any incoming message from $\mathrm{V}_{2}$.

Figure 4.23: $\mathcal{S}_{\Pi_{\text {mult }}}^{\mathrm{V}_{2}}$ : Simulator for the case of corrupt $\mathrm{V}_{2}$
We describe the simulator for the case of a corrupt a corrupt $E_{1}$. The case of a corrupt $E_{2}$ is similar to this case and hence can be worked out in a similar way.

1) $\mathcal{S}_{\Pi_{\text {bin }}}^{\mathrm{E}_{1}}$ emulates $\mathcal{F}_{\text {bic }}$ on behalf of $\mathrm{E}_{1}$ acting as the sender, for $\mu_{b^{\prime}}^{2}$. If the internal flag variable of $\mathcal{F}_{\text {bic }}$ is set to 1 , simulator $\mathcal{S}_{\Pi_{\text {bin }}}^{E_{1}}$ sets flag $=1$ and goes to step 3). Similar steps are followed for the case of $\mathrm{A}_{1}$ and $\mathrm{B}_{1}$. Additionally, $\mathcal{S}_{\Pi_{\text {bin }}}^{\mathrm{E}_{1}}$ emulates $\mathcal{F}_{\text {bic }}$ on behalf of $\mathrm{E}_{1}$ acting as the helper, for $\sigma_{b^{\prime}}^{2}$,
2) If flag $=0$ :
$-\mathcal{S}_{\Pi_{\text {bin }}}^{\mathrm{E}_{1}}$ emulates $\mathcal{F}_{\text {bic }}$ on behalf of $\mathrm{E}_{1}$, for the case of $\mu_{\mathrm{z}}^{2}$, where $\mathrm{z}=b^{\prime} \times$. If the internal flag variable of $\mathcal{F}_{\text {bic }}$ set to 1 , simulator $\mathcal{S}_{\Pi_{\text {bin }}}^{\mathrm{E}_{1}}$ sets flag ${ }^{\prime}=1$ and goes to step 3). Else the simulator invokes $\mathcal{F}_{\text {bin }}$, with inputs as $\llbracket \times \rrbracket_{E_{1}}, \llbracket b \rrbracket_{\mathrm{E}_{1}}^{\mathrm{B}}$ and $\mathbf{I}_{\mathrm{E}_{1}}$.
3) Else If flag = 1:
$-\mathcal{S}_{\Pi_{\text {bin }}}^{\mathrm{E}_{1}}$ sets $\llbracket \mathrm{x} \rrbracket_{\mathrm{E}_{1}}=(\perp, \perp, \perp), \llbracket b \rrbracket_{\mathrm{E}_{1}}^{\mathrm{B}}=(\perp, \perp, \perp)$ and invokes $\mathcal{F}_{\text {bin }}$ on behalf of $\mathrm{E}_{1}$.
$-\delta_{\Pi_{\text {bin }}}^{\mathrm{E}_{1}}$ sends the final circuit output $O$ to $\mathrm{E}_{1}$ on behalf of the pair of honest parties and discards any incoming message from $E_{1}$.

Figure 4.24: $\mathcal{S}_{\Pi_{\text {mult }}}^{\mathrm{E}_{1}}$ : Simulator for the case of corrupt $\mathrm{E}_{1}$

### 4.7 Extension to 4PC Abort

All the aforementioned robust protocols can be easily converted to the abort variant by tweaking the Bi-convey primitive (Section 3.3). In case of abort setting, parties $S_{1}$ and $S_{2}$ in the BiConvey primitive send $x$ and $\mathrm{H}(x)$ respectively to $R$, who accepts $x$ if the hashes match else aborts. Thus by swapping with the abort variant of the primitive, all the building blocks achieve security with abort. Table 4.1 provides round and communication complexity comparison of both the variants of the protocols.

| Protocol | Equation | FLASH (Abort) |  | FLASH (Robust) |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | Rounds | Comm. | Rounds | Comm. |
| Multiplication | $\llbracket \mathrm{x} \rrbracket . \llbracket \mathrm{y} \rrbracket \rightarrow \llbracket \mathrm{x} . \mathrm{y} \rrbracket$ | 2 | $6 \ell$ | 5 | $12 \ell$ |
| Dot Product | $\llbracket \overrightarrow{\mathbf{x}} \odot \overrightarrow{\mathbf{y}} \rrbracket=\llbracket \sum_{i=1}^{d} \mathrm{x}_{i} \mathrm{y}_{i} \rrbracket$ | 2 | $6 \ell$ | 5 | $12 \ell$ |
| MSB Extraction | $\llbracket x \rrbracket \rightarrow \llbracket \mathrm{msb}(\mathrm{x}) \rrbracket^{\mathrm{B}}$ | $\log \ell+4$ | $14 \ell$ | $\log \ell+5$ | $28 \ell$ |
| Truncation | $\llbracket \mathrm{x} \rrbracket . \llbracket \mathrm{y} \rrbracket \rightarrow \llbracket(\mathrm{xy})^{\mathrm{t}} \rrbracket$ | 2 | $7 \ell$ | 5 | $14 \ell$ |
| Bit Conversion | $\llbracket b \rrbracket^{\mathbf{B}} \rightarrow \llbracket b \rrbracket$ | 2 | $7 \ell$ | 5 | $14 \ell$ |
| Bit Insertion | $\llbracket b \rrbracket^{\mathbf{B}} \llbracket \mathrm{x} \rrbracket \rightarrow \llbracket b \mathrm{x} \rrbracket$ | 2 | $9 \ell$ | 5 | $18 \ell$ |

Table 4.1: Comparison of Abort and Robust variants in FLASH.

As observed in Table 4.1, for the abort setting our cost of multiplication protocol is 6 elements which turns out to be the same as [GRW18]. But from a practical viewpoint, if we cast ours and GRW18 multiplication protocol into the offline-online paradigm, where the offline phase generates the necessary offline values in order for a fast online phase to be executed when the client query becomes available, our protocol requires only 3 parties to be active $\left(V_{2}, \mathrm{E}_{1}\right.$ and $\mathrm{E}_{2}$ ) in the online phase, whereas [GRW18] needs all parties to be active throughout the entire execution.

| Work | Equation | Offline Phase |  | Online Phase |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | Rounds | Comm. | Rounds | Comm. |
| [GRW18] | $\llbracket x \rrbracket . \llbracket y \rrbracket \rightarrow \llbracket x . y \rrbracket$ | 1 | $2 \ell$ | 1 | $4 \ell$ |
| Ours |  | 1 | $3 \ell$ | 1 | $3 \ell$ |

Table 4.2: Comparison of FLASH with [GRW18] for the Abort setting.

This is helpful, because now the server associated with party $\mathrm{V}_{1}$ is only needed to generate offline values and can be shut down for the entirety of the online phase which will, in turn, save a lot in terms of monetary cost for running the server on the cloud (WAN) setting. Hence, even though the communication and round complexity of both the works turns out to be the same with respect to a single multiplication, our work has better practical efficiency in terms of the number of servers required in the online phase. Table 4.2 provides a concrete comparison of our framework with [GRW18].

## Chapter 5

## Secure Prediction

In this section, we provide detailed protocols for the prediction phase of the following ML algorithms - i) Linear Regression, ii) Logistic Regression, iii) Deep Neural Network and iv) Binarized Neural Network, using the building blocks constructed earlier in Chapter 4.

### 5.1 Our Model

We consider a server-aided setting where both model owner $M$ and client $C$ outsource their trained model parameters and query to a set of four non-colluding servers $\left\{\mathrm{V}_{1}, \mathrm{~V}_{2}, \mathrm{E}_{1}, \mathrm{E}_{2}\right\}$, in a $\llbracket \cdot \rrbracket$-shared fashion. The servers then compute the function using our 4PC protocol and finally reconstruct the result towards $C$. We assume the existence of a malicious adversary $\mathcal{A}$, who can corrupt either $M$ or $C$ and at most one among $\left\{\mathrm{V}_{1}, \mathrm{~V}_{2}, \mathrm{E}_{1}, \mathrm{E}_{2}\right\}$. Recall that $\mathbf{E}$ and $\mathbf{V}$ denote the set of servers $\left\{\mathrm{E}_{1}, \mathrm{E}_{2}\right\}$ and $\left\{\mathrm{V}_{1}, \mathrm{~V}_{2}\right\}$ respectively. We begin with the assumption that both $M$ and $C$ have already outsourced their input vectors to $\left\{\mathrm{V}_{1}, \mathrm{~V}_{2}, \mathrm{E}_{1}, \mathrm{E}_{2}\right\}$.

### 5.1.1 Notations:

We use bold smalls to denote a vector. Given a vector $\overrightarrow{\mathbf{a}}$, the $i^{\text {th }}$ element in the vector is denoted by a ${ }_{i}$. Model Owner $M$ holds a vector of trained model parameters denoted by $\overrightarrow{\mathbf{w}}$. $C$ 's query is denoted by $\overrightarrow{\mathbf{z}}$. Both $\overrightarrow{\mathbf{w}}$ and $\overrightarrow{\mathbf{z}}$ are vectors of size $d$, where $d$ denotes the number of features.

### 5.2 Linear Regression

In case of linear regression model, the output of the prediction phase for a query $\overrightarrow{\mathbf{z}}$ is given by $\overrightarrow{\mathbf{w}} \odot \overrightarrow{\mathbf{z}}=\sum_{i=1}^{d} \mathbf{w}_{i} \mathbf{z}_{i}$. Thus the prediction phase boils down to servers executing $\Pi_{\mathrm{dp}}$ protocol with inputs as $\llbracket \overrightarrow{\mathbf{w}} \rrbracket$ and $\llbracket \overrightarrow{\mathbf{z}} \rrbracket$, to obtain $\llbracket \cdot \rrbracket$ shares of $\overrightarrow{\mathbf{w}} \odot \overrightarrow{\mathbf{z}}$.

### 5.3 Logistic Regression

The prediction phase of logistic regression model for a query $\overrightarrow{\mathbf{z}}$ is given by $\operatorname{sig}(\tilde{\mathbf{w}} \odot \tilde{\mathbf{z}})$, where $\operatorname{sig}(\cdot)$ denotes the sigmoid function. The sigmoid function is defined as $\operatorname{sig}(u)=\frac{1}{1+e^{-u}}$. SecureML [MZ17] showed the drawbacks of using sigmoid function for a general MPC setting and proposed a MPC friendly approximation, defined as follows :

$$
\operatorname{sig} x(u)= \begin{cases}0 & u<-\frac{1}{2} \\ u+\frac{1}{2} & -\frac{1}{2} \leq u \leq \frac{1}{2} \\ 1 & u>\frac{1}{2}\end{cases}
$$

The above equation can also be viewed as, $\operatorname{sigx}(u)=\overline{b_{1}} b_{2}(u+1 / 2)+\overline{b_{2}}$, where bit $b_{1}=1$ if $\mathbf{u}+1 / 2<0$, bit $b_{2}=1$ if $\mathbf{u}-1 / 2<0$. Servers execute $\Pi_{\text {msb }}(\mathbf{u}+1 / 2)$ and $\Pi_{\text {msb }}(\mathbf{u}-1 / 2)$ to generate $\llbracket b_{1} \rrbracket^{\mathbf{B}}$ and $\llbracket b_{2} \rrbracket^{\mathbf{B}}$ respectively. Servers can locally compute $\llbracket \bar{b}_{i} \rrbracket^{\mathbf{B}}$ from $\llbracket b_{i} \rrbracket^{\mathbf{B}}$. After this, $\Pi_{\text {mult }}^{\mathrm{B}}\left(\llbracket \overline{b_{1}} \rrbracket, \llbracket b_{2} \rrbracket\right)$ is executed to generate $\llbracket b \rrbracket^{\mathrm{B}}$, where $b=\overline{b_{1}} b_{2}$. Servers then invoke $\Pi_{\mathrm{bin}}$ on $\llbracket b \rrbracket^{\mathbf{B}}$ and $\llbracket(\mathbf{u}+1 / 2) \rrbracket$ to generate $\llbracket \overline{b_{1}} b_{2}(\mathbf{u}+1 / 2) \rrbracket$, and $\Pi_{\mathrm{btr}}\left(\llbracket \overline{b_{2}} \rrbracket^{\mathbf{B}}\right)$ to generate $\llbracket \overline{b_{2}} \rrbracket$. Servers then locally add their shares to obtain $\llbracket \operatorname{sigx}(u) \rrbracket$. Thus the cost for one query prediction in a logistic regression model is the same as the cost of linear regression, plus the additional overhead of computing $\operatorname{sigx}(\overrightarrow{\mathbf{w}} \circ \overrightarrow{\mathbf{z}})$.

### 5.4 Deep Neural Networks (DNN)

All the techniques used to tackle the above models can be easily extended to support neural network prediction. We follow a similar procedure as ABY3, where each node across all layers, use $\operatorname{ReLU}(\operatorname{rel}(\cdot))$ as its activation function. It comprises of computation of activation vectors for all the layers of the network. The activation vector for a given layer $i$ of the network is defined as $\overrightarrow{\mathbf{a}}_{i}=\operatorname{rel}\left(\overrightarrow{\mathbf{u}}_{i}\right)$, where $\overrightarrow{\mathbf{u}}_{i}=\mathbf{W}_{i} \times \overrightarrow{\mathbf{a}}_{i-1}$ is a matrix multiplication of weight matrix $\mathbf{W}_{i}$ with the activation vector of the previous layer. Weight matrix $\mathbf{W}_{i} \in \mathbb{R}^{n_{i} \times n_{i-1}}$ contains all the weights connecting the nodes between layers $i$ and $i-1$, where $n_{i}$ represents the number nodes in layer $i$. We set matrix $\overrightarrow{\mathbf{a}}_{0}=\overrightarrow{\mathbf{z}}$, where $\overrightarrow{\mathbf{z}}$ is the input query of the client. All the above operations, that are needed for prediction, are simply a composition of several multiplications, dot products along with the evaluation of many ReLU functions. We now define the ReLU function below and also explain how to tackle it in our setting.

ReLU: The ReLU function is given as $\max (0, \mathbf{u})$. We view it as $\operatorname{rel}(\mathbf{u})=\bar{b} \mathbf{u}$, where bit $b=1$ if $\mathbf{u}<0$, and $\bar{b}$ is the complement of $b$. Servers execute $\Pi_{\text {mbb }}(\mathbf{u})$ to generate $\llbracket b \rrbracket^{\mathbf{B}}$. Servers locally compute $\llbracket \bar{b} \rrbracket^{\mathbf{B}}$ from $\llbracket b \rrbracket^{\mathbf{B}}$, followed by executing $\Pi_{\text {bin }}$ on $\llbracket \bar{b} \rrbracket^{\mathbf{B}}$ and $\llbracket u \rrbracket$ to generate $\llbracket \bar{b} u \rrbracket$.

### 5.5 Binarized Neural Network (BNN)

MOBIUS $\left[\mathrm{KCY}^{+} 18\right]$ proposed a secure prediction protocol for BNN in two party setting with one semi-honest corruption over $\mathbb{Z}_{2}$. In the original work of BNN $\left[\mathrm{HCS}^{+} 16\right]$, a batch normalization operation is performed at the output of every hidden layer of the binarized network, which requires bit-shifting mechanism. Performing bit-shifting in two party setting is very expensive. As a countermeasure, MOBIUS proposed an alternate solution for batch normalization with cost equal to that of one multiplication. The alternate solution is as follows: Suppose $x_{l}^{i}$ be the output of node $i$ in the $l^{\text {th }}$ hidden layer, instead of using bit-shifting to normalize $x_{l}^{i}$, they perform $x_{l}^{\prime i}=p_{l}^{i} x_{l}^{i}+q_{l}^{i}$, where $x_{l}^{\prime i}$ is the normalized output and $p_{l}^{i}, q_{l}^{i}$ are the normalization batch parameters for node $i$ of hidden layer $l$, which are provided by $M$.

MOBIUS also showed that this method drops the accuracy by a negligible amount. Inspired from the ideas of MOBIUS, we now provide a secure prediction protocol for our setting. Note that, $\llbracket \cdot \rrbracket$-shares of the weight matrices $\mathbf{W}_{l} \in\{-1,1\}^{n_{l} \times n_{l-1}}$, batch normalization parameters $\overrightarrow{\mathbf{p}}_{l}, \overrightarrow{\mathbf{q}}_{l}, \forall l \in\left\{1, \ldots, l_{\text {final }}\right\}$ and the query $\overrightarrow{\mathbf{z}}$ are already available among the servers.

We describe our protocol layer by layer. We use $n_{l}$ to denote the number of nodes in layer $l$. The computation in each layer $l$ consists of three stages: i) The first stage comprises of matrix multiplication $\overrightarrow{\mathbf{x}}_{l}=\mathbf{W} \mathbf{W}_{l} \times f\left(\overrightarrow{\mathbf{x}}_{l-1}^{\prime}\right)$, where $\overrightarrow{\mathbf{x}}_{l-1}^{\prime}$ denotes an $n_{l-1}$-sized vector and $f\left(\overrightarrow{\mathbf{x}}_{l-1}^{\prime}\right)$ denotes the vector obtained by applying activation function $f$ on it. The activation function for a given value a is defined as

$$
f(\mathrm{a})= \begin{cases}-1 & \mathrm{a}<0 \\ 1 & \mathrm{a} \geq 0\end{cases}
$$

The matrix multiplication can be viewed as $n_{l}$ dot product (protocol $\Pi_{\mathrm{dp}}$ ) computations. ii) Servers, then perform batch normalization process on vector $\overrightarrow{\mathbf{x}}_{l}$ to obtain $\overrightarrow{\mathbf{x}}_{l}^{\prime}=\overrightarrow{\mathbf{p}}_{l} \circ \overrightarrow{\mathbf{x}}_{l}+\overrightarrow{\mathbf{q}}_{l}$, where - denotes element wise multiplication. As evident, we use $n_{l}$ multiplications and additions to compute the $\llbracket \cdot \rrbracket$-sharing of $\overrightarrow{\mathbf{x}}_{l}^{\prime}$. iii) This stage consists of passing the $\overrightarrow{\mathbf{x}}_{l}^{\prime}$ through the activation function $f$ to obtain $f\left(\overrightarrow{\mathbf{x}}_{l}^{\prime}\right)$.

To compute the activation function $f(\mathrm{a})$ in a $\llbracket \cdot \rrbracket$-shared fashion, servers execute $\Pi_{\text {msb }}$ on $\llbracket a \rrbracket$ to extract the $\operatorname{MSB} \operatorname{msb}(a)$, followed by executing $\Pi_{b t r}$ on $\llbracket \operatorname{msb}(a) \rrbracket^{B}$ to generate $\llbracket \mathrm{msb}(\mathrm{a}) \rrbracket$. Finally, the servers locally compute $\llbracket f(\mathrm{a}) \rrbracket=2 \llbracket \mathrm{msb}(\mathrm{a}) \rrbracket-1$. For the input layer $(l=0)$, servers set $f\left(\overrightarrow{\mathbf{x}}_{0}^{\prime}\right)=\overrightarrow{\mathbf{z}}$. Note that stage three is not required at the output layer.

## Chapter 6

## Implmentation

We show the practicality of our framework by providing implementation results and compare with ABY 3 , in their respective settings over a ring of $\mathbb{Z}_{2^{64}}$.

### 6.1 Experimental Setup:

Our experiments have been carried out both in the LAN and WAN setting. In the LAN setting, our machines are equipped with Intel Core i7-7790 CPU with 3.6 GHz processor speed and 32 GB RAM. Each of the four cores were able to handle eight threads, resulting in a total of 32 threads. We had a bandwidth of 1 Gbps and an average round-trip time ( rtt ) of $\approx 0.26 \mathrm{~ms}$. In the WAN setting, we use Microsoft Azure Cloud Services (Standard D8s v3, 2.4 GHz Intel Xeon® E5-2673 v3 (Haswell), 32GB RAM, 8 vcpus) with machines located in North Central US $\left(S_{1}\right)$, South East Asia $\left(S_{2}\right)$, Australia East $\left(S_{3}\right)$ and West Europe $\left(S_{4}\right)$. Each of the eight cores was capable of handling 16 threads resulting in a total of 128 threads. The bandwidth was limited to 20 Mbps and the average rtt times are as follows:

| $S_{1}-S_{2}$ | $S_{1}-S_{3}$ | $S_{1}-S_{4}$ | $S_{2}-S_{3}$ | $S_{2}-S_{4}$ | $S_{3}-S_{4}$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 161.76 ms | 197.03 ms | 97.32 ms | 116.36 ms | 225.34 ms | 236.56 ms |

We build on the ENCRYPTO library [CaTD17], following the standards of $\mathrm{C}++11$. Due to the unavailability of the code of ABY3 [MR18], we implement their framework for comparison. For our executions, we report the average values over a run of 15 times. Flash Implementation provides the link for our code.

### 6.1.1 Parameters for Comparison:

We consider three parameters for comparison- a) Latency (calculated as the maximum runtime of the servers), b) Communication complexity and c) Throughput (number of operations per unit time). The latency and throughput are evaluated over both LAN and WAN settings. The communication complexity is measured independent of the network. For the aforementioned algorithms, the throughput is calculated as the number of queries that can be computed per second and min in LAN and WAN respectively.

### 6.1.2 Server Assignment:

We assign the roles to the servers to maximize the performance of each of the frameworks, that we use for benchmarking. The table below provides the assignment of roles to the corresponding servers. For the 4 PC setting, $\mathrm{V}_{1}, \mathrm{~V}_{2}$ represent the set of verifiers while $\mathrm{E}_{1}, \mathrm{E}_{2}$ represent the set of evaluators. $P_{0}, P_{1}, P_{2}$ represent the parties, in the 3 PC setting. we omit comparison with ASTRA framework as ABY3 outperforms ASTRA in terms of total communication (ref. Table 1.1).

| Work | $S_{1}$ | $S_{2}$ | $S_{3}$ | $S_{4}$ |
| :---: | :---: | :---: | :---: | :---: |
| FLASH | $\mathrm{E}_{1}$ | $\mathrm{E}_{2}$ | $\mathrm{~V}_{1}$ | $\mathrm{~V}_{2}$ |
| ABY3 | $P_{1}$ | $P_{2}$ | $P_{3}$ | - |

Table 6.1: Server Assignment for FLASH and ABY3 frameworks

### 6.1.3 Datasets:

We pick real-world datasets to measure the throughput for the prediction phase. The datasets we pick have features ranging from 13 to 784 , which cover a range of feature sizes for a wide span of commonly used datasets.

For Linear Regression, we use Boston Housing Prices Dataset (Boston) [HR78] and the dataset obtained from [NOA17] about the Weather Conditions in World War Two (Weather). The Boston dataset has $\approx 500$ samples, each with 14 features, while the Weather dataset has $\approx 119,000$ samples with 31 features.

For Logistic Regression we use the dataset from [Dar17] which categorizes and gives the rating for recipes (Recipes) and Candy Power Ranking (Candy) dataset from [Hic17] which predicts the most popular Halloween candy. The Candy dataset is small with only 13 features and $\approx 85$ samples whereas the Recipe dataset is large with 680 features and $\approx 20,000$ samples.

| ML Algorithm | Dataset | \#features | \#samples |
| :---: | :--- | ---: | ---: |
| Linear Reg. | Boston Housing Prices [HR78] | 14 | $\approx 500$ |
|  | Weather Conditions [NOA17] | 31 | $\approx 119000$ |
| Logistic Reg. | Candy Power Ranking [Hic17] | 13 | $\approx 85$ |
|  | Food Recipes [Dar17] | 680 | $\approx 20000$ |
| DNN \& BNN | MNIST [LC10] | 784 | $\approx 70000$ |

Table 6.2: Real World datasets for Comparison

For Deep Neural Network and Binarized Neural Network, we use MNIST [LC10] dataset which contains 784 pixel images of handwritten numbers, each of size $28 \times 28$. We also use synthetic datasets as it provides freedom to tune the number of features parameter and showcase the improvement with increasing feature size.

### 6.2 ML Building Blocks

We begin by comparing our protocols for some of the crucial ML building blocks, namely i) Dot Product, ii) MSB Extraction and iii) Truncation, against the state of the art protocols of ABY3 [MR18]. The comparison is mainly to show the substantial improvement we achieve in each building block when we shift from 3PC to 4PC setting, along with robustness guarantee. Later in Section 6.3 and 6.4 we show how the improvement in these blocks help us achieve massive improvements (Table.1.2) for our ML algorithms.

### 6.2.1 Dot Product:

Dot Product is one of the vital building blocks for many machine learning algorithms like Linear Regression, Logistic Regression and Neural Network to name a few.

| Work | LAN Latency $(m s)$ | WAN Latency $(s)$ |
| :---: | :---: | :---: |
| ABY3 | 3.55 | 1.10 |
| FLASH | 1.51 | 1.08 |

Table 6.3: Latency of 1 dot product computation for 784 features

Table 6.3 gives the comparison of our work with ABY3 with respect to the completion of one dot product computation for $d=784$ features. We observe that for the LAN setting, even though the number of rounds required for completion of one dot product execution for both
frameworks is 5 rounds, the latency of ABY3 is still twice of our FLASH. This discrepancy happens because the rtt of the network varies drastically with increase in the size of communication. In case of ABY 3 , due to their dot product protocol being dependent on the number of features the per party communication turns out to be 42.8 KB , whereas our protocol incurs a tiny cost of 0.09 KB . Such a discrepancy is not observed in WAN as the communication threshold to vary the rtt is very high, under which all our protocols operate. We also plot the number of dot product computations that can be performed per sec, for varying feature sizes.

Figure 6.1: \# of dot product computations with increasing features.

It is clear from Figure.6.1 that varying the number of features has minimal impact on our throughput, since the communication cost of ours is independent of the feature size, while ABY3 suffers with increase in number of features. Thus for any machine learning algorithm which is heavily dependent on dot product computations, our protocol outperforms ABY3.

### 6.2.2 MSB Extraction:

MSB Extraction is the crux for many classification algorithms. Deep Neural Network and Binarized Neural Network where a large number of sequential comparisons are required. Table 6.4 gives the comparison of our work with ABY3, with respect to the completion of one MSB Extraction.

| Work | LAN Latency $(m s)$ | WAN Latency $(s)$ |
| :---: | :---: | :---: |
| ABY3 | 3.53 | 2.22 |
| FLASH | 3.51 | 2.28 |

Table 6.4: Latency for single execution of MSB Extraction protocol

We also provide a latency graph with respect to the number of sequential comparisons.

Figure 6.2: Latency with increasing sequential comparisons

We observe from Figure 6.2 that the time taken for both protocols to complete a set of sequential comparisons are almost similar. Our completion time for sequential comparisons is slightly more than ABY3 in the WAN setting as the average rtts across the three servers (Table 6.1) in case of ABY3 is lesser as compared to ours where we require all four servers. Note that we omit the plot for the LAN setting as the average rtts between all servers are almost identical leading to both the plotted lines to practically overlap. Even though the average completion time for the both are almost identical, we require a communication cost of only $\approx 0.19 \mathrm{~KB}$ per comparison as opposed to ABY3's cost of $\approx 0.33 \mathrm{~KB}$. Thus, for the prediction phase of an ML algorithm like Deep Neural Network, the gap in the communication cost will keep growing bigger with the increase in the number of hidden nodes in the neural network.

### 6.2.3 Truncation:

To showcase the effect of our efficient truncation protocol, we compare our protocol with that of ABY3. Table 6.5 gives the comparison with respect to the completion of a single execution of the protocol.

| Work | LAN Latency $(m s)$ | WAN Latency $(s)$ |
| :---: | :---: | :---: |
| ABY3 | 1.52 | 1.11 |
| FLASH | 1.51 | 1.07 |

Table 6.5: Latency for a single execution of Truncation protocol
In the case of ABY3, though the truncation protocol takes $2 \ell-1$ rounds, the latency of both the frameworks in Table.6.5 are almost identical. This is because the goal of ABY3 was to have
a high throughput framework, thus they compute $\approx 2^{20}$ parallel instances of $\left([r], \llbracket r^{\mathrm{t}} \rrbracket\right)$ pairs so that the amortized time for a single execution of truncation protocol reduces. On the flip side, we do not have any such restriction on the number of ( $[\mathrm{r}], \llbracket \mathrm{r} \mathrm{r} \rrbracket$ ) pair instances and the latency remains the same even if only one pair is required. Table 6.6 provides the throughput, measured as the number of multiplications with truncation performed, over both LAN (\#mult/sec) and WAN (\#mult/min) settings.

| Work | LAN |  | WAN |  |
| :---: | :---: | :---: | :---: | :---: |
|  | \#mult/sec | Improv. | \#mult/min | Improv. |
| ABY3 | 0.45 M | $\mathbf{8 . 8} \times$ | 4.76 M | $\mathbf{8 . 8 1} \times$ |
| FLASH | 3.97 M |  | 0.54 M |  |

Table 6.6: Throughput Comparison wrt \# multiplications with truncation
We observe a minimum improvement of $8.8 \times$ over ABY3. The improvement comes from the fact that ABY 3 requires $\approx 6300$ bits per truncation as compared to 896 bits for our case, when instantiated over a 64 bit ring. Our protocol will outperform ABY3 for all the ML algorithms that require repeated multiplications in the prediction phase.

### 6.3 Linear and Logistic Regression

In this section, we compare the concrete improvement of our framework against ABY3, for Linear and Logistic Regression. The performance is reported in terms of throughput of the protocol, the units being \# queries/sec over LAN and \# queries/min over WAN.

| Setting | \# Features | Ref. | Linear Reg. | Logistic Reg. |
| :---: | :---: | :---: | :---: | :---: |
| $\begin{aligned} & \text { LAN } \\ & (m s) \end{aligned}$ | 10 | ABY3 | 1.67 | 5.57 |
|  |  | FLASH | 1.53 | 5.36 |
|  | 100 | ABY3 | 2.05 | 5.91 |
|  |  | FLASH | 1.49 | 5.37 |
|  | 1000 | ABY3 | 3.61 | 7.55 |
|  |  | FLASH | 1.54 | 5.39 |
| WAN (sec) | 10/100/1000 | ABY3 | 1.12 | 3.77 |
|  |  | FLASH | 1.09 | 3.73 |

Table 6.7: Latency of frameworks for Linear and Logistic Reg.

We begin by comparing our framework with ABY3 over synthesized datasets as it provides us the freedom to tune the number of features parameter and showcase the improvement with the increase in \#features. Table 6.7 provides a throughput comparison for $\#$ features $d=10,100$ and 1000 .

```
\squareFLASH}\square\textrm{ABY}
```

Figure 6.3: Throughput Comparison (\# queries/sec) for Linear and Logistic Regression in LAN setting

$$
\cdot 10^{5}
$$

Figure 6.4: Throughput Comparison (\# queries/min) for Linear and Logistic Regression in WAN setting

As mentioned earlier in Section.6.2.1, the increase in feature size changes the LAN latency for ABY3 from 1.68 ms to 3.63 ms and 5.59 ms to 7.54 ms for Linear and Logistic regression respectively, whereas our latency stays stable to $\approx 1.5 \mathrm{~ms}$ and $\approx 5.36 \mathrm{~ms}$ for the same. The
reason for the stability in our latency is the underlying dot product which is independent of the feature size.

We now test on real-world datasets as mentioned in Table 6.2 for Linear and Logistic Regression. Figures 6.3 and 6.4 provide a comparison with ABY3 in terms of the number of queries computed per second and minute in LAN and WAN setting respectively. For Linear Regression, we observe a minimum throughput gain of $\approx 35 \times$. The improvement primarily comes from the underlying $\Pi_{\mathrm{dp}}$ protocol and its independence of feature size property. Similarly, for Logistic Regression, we observe a throughput gain of around $29 \times$, where protocols $\Pi_{d p}$ and $\Pi_{\text {msb }}$ become the prime contributors for the improvements in Logistic Regression.

### 6.4 Deep and Binarized Neural Network

In this section, we compare our framework with ABY3, for DNN and BNN. The accuracy of our predictions has the same bit-error that ABY3 mentions due to the similarity in the approach to truncation. We begin by comparing (Table 6.8) over synthesized datasets and show the improvement in terms of latency for $\#$ features $d=10,100$ and 1000 .

| Setting | \# Features | Ref. | DNN | BNN |
| :---: | :---: | :---: | :---: | :---: |
| 10 | ABY3 | 58.98 | 59.18 |  |
|  |  | FLASH | 28.78 | 31.46 |
|  | 100 | ABY3 | 67.79 | 67.83 |
|  |  | FLASH | 28.86 | 31.71 |
|  | 1000 | ABY3 | 146.42 | 147.22 |
|  |  | FLASH | 29.04 | 31.98 |
| WAN | $10 / 100 / 1000$ | ABY3 | 13.67 | 13.68 |
|  |  | 12.59 | 14.21 |  |

Table 6.8: Latency of frameworks for DNN and BNN

Figure 6.5 also shows how the depth of the neural network affects the throughput of the two frameworks. We consider a neural network with each hidden layer having 128 nodes and the final output layer having 10 nodes. The network is tested on MNIST dataset with $d=784$ features.

It is clear from Figure 6.5, that we achieve impressive throughput gains of $\approx 155 \times$ and $\approx 8.5 \times$ for LAN and WAN setting respectively, even when the depth of the neural network goes up to 8 hidden layers. Such massive improvements primarily come from amalgamation of the improvements observed in the underlying building blocks (Section 6.2). Similar to DNN,

Figure 6.5: Throughput Comparison for DNN with increasing number of hidden layers.
we also achieve similar massive improvements for the case of BNN due to the aforementioned reasons. When tested on MNIST dataset ( $d=784$ features) for a BNN having 2 hidden layers, we observed throughput gains of $\approx 268 \times$ in LAN and $\approx 11.5 \times$ in WAN setting.
